Chapter 1

Indices of functions by subject

1.1 Library Functions

1.1.1 Image Object

- ChangeDataType Change the data type of an image
- ChangeDimensions Changes the order of the dimensions in an image
- ChangeToOd Make an image zero dimensional
- HasContiguousData Determines whether an image has all data contiguous in memory
- HasNormalStride Determines whether an image has a normal stride
- ImageAssimilate Inherit properties of another image
- ImageCopyProperties Copy the properties of an image
- ImageForge Allocate pixel data for an image
- ImageFree Free an image
- ImageGetData Get the data pointers of a set of images
- ImageGetDataType Read the data type field
- ImageGetDimensionality Read the dimensionality field
- ImageGetDimensions Read the dimensions array
- ImageGetPlane Read the plane number
- ImageGetStride Read the stride array
- ImageGetType Read the type field
- ImageNew Allocate a structure
- ImagesCheck Check properties of several images
- ImagesCheckTwo Check properties of two images
- ImagesCompare Compare properties of several images
- ImagesCompareTwo Compare properties of two images
- ImageSetDataType Set the data type field
- ImageSetDimensions Set the dimensions array
- ImageSetType Set the image type field
- ImagesSeparate Take care of in-place operations
- ImageStrip Restore an image to its initial ("raw") state

1.1.2 Scalar Images

- ConvertDataType Converts the data type of an image
- IsScalar Determines whether an image is a scalar
- ScalarImageNew Allocate a scalar image

1.1.3 Strings

- StringAppend Append a string to another
- StringArrayCopy Copy a string array
- StringArrayFree Array free function
- StringArrayNew Allocate an array of strings
- StringCat Concatenate two strings
- StringCompare Compare two strings
- StringCompareCaseInsensitive Compare two strings without minding case
- StringCopy Copy a String
- StringCrop Crop a string
- StringFree Free a string
- StringNew Allocate a string
- StringReplace Replace the contents of one string with that of another
- UnderscoreSpaces Replace spaces with underscores

1.1.4 Arrays

- ArrayFree Array free function
- ArrayNew Array allocation function
- BooleanArrayCopy Copy an array
- BooleanArrayFind Find value in array
- BooleanArrayFree Array free function
- BooleanArrayNew Array allocation function
- BoundaryArrayFree Array free function
- BoundaryArrayNew Array allocation function

- ComplexArrayCopy Copy an array
- ComplexArrayFind Find value in array
- ComplexArrayFree Array free function
- ComplexArrayNew Array allocation function
- ConvertArray converts the data type of an array
- CoordinateArrayFree Array free function
- CoordinateArrayNew Array allocation function
- DataTypeArrayCopy Copy an array
- DataTypeArrayFind Find value in array
- DataTypeArrayFree Array free function
- DataTypeArrayNew Array allocation function
- FloatArrayCopy Copy an array
- FloatArrayFind Find value in array
- FloatArrayFree Array free function
- FloatArrayNew Array allocation function
- FrameWorkProcessArrayFree Array free function
- FrameWorkProcessArrayNew Array allocation function
- ImageArrayFree Array free function
- ImageArrayNew Array allocation function
- ImageCheckBooleanArray Check a boolean array
- ImageCheckBoundaryArray Check a boundary array
- ImageCheckComplexArray Check a complex array
- ImageCheckFloatArray Check a float array
- ImageCheckIntegerArray Check an integer array
- IntegerArrayCopy Copy an array
- IntegerArrayFind Find value in array
- IntegerArrayFree Array free function
- IntegerArrayNew Array allocation function
- StringArrayCopy Copy a string array

- StringArrayFree Array free function
- StringArrayNew Allocate an array of strings
- VoidPointerArrayCopy Copy an array
- VoidPointerArrayFind Find value in array
- VoidPointerArrayFree Array free function
- VoidPointerArrayNew Array allocation function

1.1.5 Frameworks

- MonadicFrameWork FrameWork for monadic operations
- PixelTableFrameWork FrameWork for PixelTable filters
- ScanFrameWork FrameWork for scanning multiple images
- SeparableFrameWork FrameWork for separable filters
- SingleOutputFrameWork FrameWork for generation functions

1.1.6 Pixel Tables

- BinaryImageToPixelTable Convert a binary image to a pixel table
- GreyValuesInPixelTable Copy greyvalues from image in pixel table
- PixelTableAddRun Add a new run to a pixel table
- PixelTableCreateFilter Create a pixel table from a filter shape
- PixelTableFrameWork FrameWork for PixelTable filters
- PixelTableGetDimensionality Get the dimensionality of a pixel table
- PixelTableGetDimensions Get the dimensions of a pixel table
- PixelTableGetOffsetAndLength Converts the pixel table's runs
- PixelTableGetOrigin Get the origin of the pixel table
- PixelTableGetPixelCount Get the number of pixels encoded in the pixel table
- PixelTableGetRun Get the contents of a pixel table run
- PixelTableGetRuns Get the number of runs in a pixel table
- PixelTableGetSize The number of pixels in the pixel table's bounding box
- PixelTableNew Allocate a new pixel table

- PixelTableSetRun Initialises a pixel table run
- PixelTableShiftOrigin Changes the origin of the pixel table
- PixelTableToBinaryImage Convert a pixel table to a binary image

1.1.7 Data Structures

- PixelHeapFree Destroy heap structure
- PixelHeapIsEmpty Query heap
- PixelHeapNew Create a new heap structure
- PixelHeapPop Pop item onto heap
- PixelHeapPush Push item onto heap
- PixelQueueFree Destroy queue structure
- PixelQueueIsEmpty Query queue
- PixelQueueNew Create a new queue structure
- PixelQueuePop Pop item from queue
- PixelQueuePush Push item onto queue
- StablePixelHeapFree Destroy heap structure
- StablePixelHeapIsEmpty Query heap
- StablePixelHeapNew Create a new heap structure
- StablePixelHeapPop Pop item onto heap
- StablePixelHeapPush Push item onto heap

1.1.8 Numerical Algorithms

• OneDimensionalSearch - Numerical algorithm

1.1.9 Sorting

- DistributionSort Sort a block of data
- DistributionSortIndices Sort indices to block of data
- DistributionSortIndices16 Sort indices to a block of data
- GetRank Value selection function

- ImageSort Sort image data
- ImageSortIndices Sort indices to image data
- InsertionSort Sort a block of data
- InsertionSortIndices Sort indices to a block of data
- InsertionSortIndices16 Sort indices to a block of data
- QuickSort Sort a block of data
- QuickSortAnything Sort data of any type
- QuickSortIndices Sort indices to a block of data
- QuickSortIndices16 Sort indices to a block of data
- Sort Sort a block of data
- SortAnything Sort data of any type
- SortCompareFunction Typedef for comparison function (sorting)
- SortIndices Sort indices to a block of data
- SortIndices16 Sort indices to a block of data
- SortSwapFunction Typedef for swap and copy function (sorting)

1.1.10 Indexing

- CoordinateToIndex Convert coordinate to pixel index
- dip_PixelGetFloat Midlevel PixelIO function
- dip_PixelGetInteger Midlevel PixelIO function
- dip_PixelSetFloat Midlevel PixelIO function
- dip_PixelSetInteger Midlevel PixelIO function
- Get Get a pixel value
- GetComplex Get complex pixel value
- GetFloat Get float pixel value
- GetInteger Get integer pixel value
- IndexToCoordinate Convert pixel index to coordinate
- IndexToCoordinateWithSingletons Convert pixel index to coordinate
- NeighbourIndicesListMake Get indices to direct neighbours

- NeighbourListMake Get list of direct neighbours
- NeighbourListMakeChamfer Get list of neighbours based on Chamfer metric
- NeighbourListMakeImage Get list of neighbours based on metric in image
- NeighbourListToIndices Get indices to neighbours
- Set the value of a pixel
- SetComplex Set a pixel value
- SetFloat Set a pixel value
- SetInteger Set a pixel value

1.1.11 Memory Management

- MemoryCopy Copy memory blocks
- MemoryFree Free a chunk of memory
- MemoryFunctionsSet Sets memory allocation functions
- MemoryNew Allocate and track memory
- MemoryReallocate Reallocate a chunk of memory
- ResourcesFree Free resources
- ResourcesMerge Add one resource list to another
- ResourcesNew Allocate a resource tracking structure
- ResourceSubscribe Track a resource
- ResourceUnsubscribe Stop tracking a resource

1.1.12 Support Functions

- DataTypeAllowed Check whether a data type is allowed
- DataTypeGetInfo Get information about a data type
- error.h Contains error messages
- ErrorFree Free a DIPlib call tree
- Exit Clean up before exiting
- FillBoundaryArray Fill the border of array according to the boundary condition
- GetLibraryInformation Support function

- GetUniqueNumber Obtain an unique value
- GlobalBoundaryConditionGet Get global Boundary Conditions
- GlobalBoundaryConditionSet Set global boundary conditions
- GlobalFilterShapeGet Get global filter shape value
- GlobalFilterShapeSet Set the global filter shape value
- GlobalGaussianTruncationGet Get the global gaussian truncation
- GlobalGaussianTruncationSet Set the global gaussian truncation
- Initialise Initialise DIPlib
- macros.h Various macros
- ovl.h Call an overloaded function
- Physical Dimensions Copy Copy a Physical Dimensions
- Physical Dimensions Free Free a Physical Dimensions data structure
- Physical Dimensions Is Isotropic Checks if the Physical Dimensions are isotropic
- Physical Dimensions New Allocates a new Physical Dimensions structure
- Register Generic registry function
- RegisterClass Register a registry class
- RegistryArrayNew Allocate a registry array
- RegistryGet Get a registry item
- RegistryList Get an array of registry IDs
- RegistryValid Validate an registry item
- TimerGet Timing functions
- TimerSet Timing functions
- tpi.h Type iterator
- Unregister Remove a registry item

1.2 File I/O functions

1.2.1 File IO

• Colour2Gray - Convert ND image with colour information to a (n-1)D grayvalue image (in dipIO)

- ImageFileGetInfo Get information about image in file (in dipIO)
- ImageFileInformationFree Free a Image File Information structure (in dipIO)
- ImageFileInformationNew Allocate an Image File Information structure (in dipIO)
- ImageIsGIF Confirm that a file is a GIF file (in dipIO)
- ImageIsICS Confirm that a file is an ICS file (in dipIO)
- ImageIsJPEG Confirm that a file is a JPEG file (in dipIO)
- ImageIsLSM Confirm that a file is a Zeiss LSM file (in dipIO)
- ImageIsTIFF Confirm that a file is a TIFF file (in dipIO)
- ImageRead Read grey-value image from file (in dipIO)
- ImageReadColour Read colour image from file (in dipIO)
- ImageReadCSV Read comma-separated values from file (in dipIO)
- ImageReadCSVInfo Get information about image in comma-separated values file (in dipIO)
- ImageReadGIF Read a GIF image from file (in dipIO)
- ImageReadGIFInfo Get information about image in GIF file (in dipIO)
- ImageReadICS Read ICS image from file (in dipIO)
- ImageReadICSInfo Get information about image in ICS file (in dipIO)
- ImageReadJPEG Read JPEG image from file (in dipIO)
- ImageReadJPEGInfo Get information about image in JPEG file (in dipIO)
- ImageReadLSM Read Zeiss LSM image from file (in dipIO)
- ImageReadLSMInfo Get information about image in LSM file (in dipIO)
- ImageReadPIC Read BioRad PIC image from file (in dipIO)
- ImageReadPICInfo Get information about image in BioRad PIC file (in dipIO)
- ImageReadROI Read a portion of a grey-value image from file (in dipIO)
- ImageReadTIFF Read TIFF image from file (in dipIO)

- ImageReadTIFFInfo Get information about image in TIFF file (in dipIO)
- ImageWrite Write grey-value image to file (in dipIO)
- ImageWriteColour Write colour image to file (in dipIO)
- ImageWriteCSV Write image to a comma-separated-value file (in dipIO)
- ImageWriteEPS Write image to Encapsulated PostScript file (in dipIO)
- ImageWriteFLD Write image to AVS field file (in dipIO)
- ImageWriteGIF Write image to a GIF file (in dipIO)
- ImageWriteICS Write ICS image to file (in dipIO)
- ImageWriteJPEG Write JPEG image to file (in dipIO)
- ImageWritePS Write image to PostScript file (in dipIO)
- ImageWriteTIFF Write TIFF image to file (in dipIO)
- MeasurementRead Read measurement results from a file
- MeasurementWrite Write measurement results to a file
- MeasurementWriteCSV Write measurement results to a CSV file
- MeasurementWriteHTML Write measurement results to an HTML file
- MeasurementWriteText Write measurement results as readable text

1.3 Image Processing Functions

1.3.1 Mathematics

- Abs Arithmetic function
- Acos trigonometric function
- Add arithmetic function
- AddComplex arithmetic function
- AddFloat arithmetic function
- And logic operation
- Asin trigonometric function
- Atan trigonometric function
- Atan2 arithmetic function
- BesselJO mathematical function

- BesselJ1 mathematical function
- BesselJN mathematical function
- BesselYO mathematical function
- BesselY1 mathematical function
- BesselyN mathematical function
- Ceil Arithmetic function
- Compare Compare grey values in two images
- Cos trigonometric function
- Cosh trigonometric function
- CumulativeSum statistics function
- Div arithmetic function
- DivComplex arithmetic function
- DivFloat arithmetic function
- Equal Compare grey values in two images
- Erf mathematical function
- Erfc mathematical function
- Exp arithmetic function
- Exp10 arithmetic function
- Exp2 arithmetic function
- Floor Arithmetic function
- Fraction Arithmetic function
- GetMaximumAndMinimum statistics function
- Greater Compare grey values in two images
- IDivergence difference measure
- Imaginary Arithmetic function
- Invert logic operation
- Lesser Compare grey values in two images
- Ln arithmetic function
- LnGamma mathematical function

- LnNormError difference measure
- Log10 arithmetic function
- Log2 arithmetic function
- Max arithmetic function
- MaxFloat arithmetic function
- Maximum statistics function
- mBesselJO mathematical function
- mBesselJ1 mathematical function
- mBesselJN mathematical function
- mBesselYO mathematical function
- mBesselY1 mathematical function
- mBesselYN mathematical function
- Mean statistics function
- MeanAbsoluteError difference measure
- MeanError difference measure
- MeanModulus statistics function
- MeanSquareError difference measure
- MeanSquareModulus statistics function
- Median statistics function
- mErf mathematical function
- mErfc mathematical function
- mExp10 mathematical function
- \bullet mExp2 mathematical function
- mFraction mathematical function
- mGammaP mathematical function
- mGammaQ mathematical function
- Min arithmetic function
- MinFloat arithmetic function
- Minimum statistics function

- mLnGamma mathematical function
- mLog2 mathematical function
- mNearestInt mathematical function
- Modulo Arithmetic function
- Modulus Arithmetic function
- mReciprocal mathematical function
- mSign mathematical function
- mSinc mathematical function
- mTruncate mathematical function
- Mul arithmetic function
- MulComplex arithmetic function
- MulFloat arithmetic function
- NearestInt Arithmetic function
- NormaliseSum Normalise the sum of the pixel values
- NotEqual Compare grey values in two images
- NotGreater Compare grey values in two images
- NotLesser Compare grey values in two images
- Or logic operation
- Percentile statistics function
- Phase Arithmetic function
- RadialMaximum statistics function
- RadialMean statistics function
- RadialMinimum statistics function
- RadialSum statistics function
- Real Arithmetic function
- Reciprocal arithmetic function
- RootMeanSquareError difference measure
- Select Configurable selection function
- Sign Arithmetic function

- Sin trigonometric function
- Sinc mathematical function
- Singular Value Decomposition Singular value decomposition
- Sinh trigonometric function
- Sqrt arithmetic function
- StandardDeviation statistics function
- Sub arithmetic function
- SubComplex arithmetic function
- SubFloat arithmetic function
- Sum statistics function
- SumModulus statistics function
- Tan trigonometric function
- Tanh trigonometric function
- TensorImageInverse Invert tensor image
- Truncate Arithmetic function
- Variance statistics function
- WeightedAdd arithmetic function
- WeightedDiv arithmetic function
- WeightedMul arithmetic function
- WeightedSub arithmetic function
- Xor logic operation

1.3.2 Statistics

- ChordLength Compute the chord lengths of the different phases
- CumulativeSum statistics function
- GetMaximumAndMinimum statistics function
- IDivergence difference measure
- LnNormError difference measure
- Maximum statistics function

- Mean statistics function
- MeanAbsoluteError difference measure
- MeanError difference measure
- MeanModulus statistics function
- MeanSquareError difference measure
- MeanSquareModulus statistics function
- Median statistics function
- Minimum statistics function
- PairCorrelation Compute the pair correlation function
- Percentile statistics function
- ProbabilisticPairCorrelation Compute the probabilistic pair correlation function
- RadialMaximum statistics function
- RadialMean statistics function
- RadialMinimum statistics function
- RadialSum statistics function
- RootMeanSquareError difference measure
- StandardDeviation statistics function
- Sum statistics function
- SumModulus statistics function
- Variance statistics function

1.3.3 Manipulation

- Crop Remove the outer parts of an image
- dip_PixelGetFloat Midlevel PixelIO function
- dip_PixelGetInteger Midlevel PixelIO function
- dip_PixelSetFloat Midlevel PixelIO function
- dip_PixelSetInteger Midlevel PixelIO function
- ExtendRegion Image manipulation functions
- Get Get a pixel value

- GetComplex Get complex pixel value
- GetFloat Get float pixel value
- GetInteger Get integer pixel value
- GetLine Get a line from an image
- GetSlice Get a slice from an image
- Map Remaps an image
- Mirror Mirrors an image
- PutLine Put a line in an image
- PutSlice Put a slice in an image
- Resampling Interpolation function
- Rotation Interpolation function
- Rotation3d Interpolation function
- Rotation3d_Axis Interpolation function
- Set the value of a pixel
- SetComplex Set a pixel value
- SetFloat Set a pixel value
- SetInteger Set a pixel value
- Shift an image manipulation function
- Skewing Interpolation function
- Subsampling Interpolation function
- Wrap Wrap an image

1.3.4 Interpolation

- Resampling Interpolation function
- Rotation Interpolation function
- Rotation3d Interpolation function
- Rotation3d_Axis Interpolation function
- Skewing Interpolation function
- SubpixelLocation Gets coordinates of an extremum with sub-pixel precision

- SubpixelMaxima Gets coordinates of local maxima with sub-pixel precision
- SubpixelMinima Gets coordinates of local minima with sub-pixel precision
- Subsampling Interpolation function

1.3.5 Painting

- PaintBox Paint a box
- PaintDiamond Paint a diamond-shaped object
- PaintEllipsoid Paint an ellipsoid

1.3.6 Linear Filters

- Convolve1d Perform a 1D convolution
- ConvolveFT Fourier transform—based convolution filter
- Derivative Derivative filter
- FiniteDifference A linear gradient filter
- FiniteDifferenceEx A linear gradient filter
- GaborIIR Infinite impulse response filter
- Gauss Gaussian Filter
- Gaussian Filter through the Fourier Domain
- Gaussiir Infinite impulse response filter
- GeneralConvolution Genaral convolution filter
- Laplace Second order derivative filter
- SeparableConvolution FrameWork for separable convolution filters
- Sharpen Enhance an image
- SobelGradient A linear gradient filter
- Uniform Uniform filter

1.3.7 Derivative Filters

- Derivative Derivative filter
- Dgg Second order derivative filter
- FiniteDifference A linear gradient filter
- FiniteDifferenceEx A linear gradient filter
- Gaussian Filter
- Gaussett Gaussian Filter through the Fourier Domain
- GradientDirection2D Derivative filter
- GradientMagnitude Derivative filter
- Laplace Second order derivative filter
- LaplaceMinDgg Second order derivative filter
- LaplacePlusDgg Second order derivative filter
- SobelGradient A linear gradient filter

1.3.8 Non-Linear Filters

- BiasedSigma Adaptive edge sharpening & contrast enhancing filter
- Closing Morphological closing operation
- Dilation Local maximum filter
- Erosion Local minimum filter
- GaussianSigma Adaptive Gaussian smoothing filter
- GeneralisedKuwahara Generalised Kuwahara filter
- Generalised Kuwahara Improved Generalised Kuwahara filter
- Kuwahara Edge perserving smoothing filter
- KuwaharaImproved Edge perserving smoothing filter
- MedianFilter Non-linear smoothing filter
- MorphologicalSmoothing Morphological smoothing filter
- Opening Morphological opening operation
- PercentileFilter Rank-order filter
- Sigma Adaptive uniform smoothing filter
- VarianceFilter Sample Variance Filter

1.3.9 Binary Filters

- BinaryClosing Binary morphological closing operation
- BinaryDilation Binary morphological dilation operation
- BinaryErosion Binary morphological erosion operation
- BinaryOpening Binary morphological opening operation
- BinaryPropagation Morphological propagation of binary objects
- EdgeObjectsRemove Remove binary edge objects
- EuclideanSkeleton binary skeleton operation
- GrowRegions Dilate the regions in a labelled image
- Label Label a binary image

1.3.10 Mathematical Morphology

- AreaOpening Morphological filter
- BinaryClosing Binary morphological closing operation
- BinaryDilation Binary morphological dilation operation
- BinaryErosion Binary morphological erosion operation
- BinaryOpening Binary morphological opening operation
- BinaryPropagation Morphological propagation of binary objects
- Closing Morphological closing operation
- Dilation Local maximum filter
- DirectedPathOpening Morphological filter
- EdgeObjectsRemove Remove binary edge objects
- Erosion Local minimum filter
- EuclideanSkeleton binary skeleton operation
- GrowRegions Dilate the regions in a labelled image
- GrowRegionsWeighted Grow labelled regions using grey-weighted distances
- Lee Morphological edge detector
- LocalMinima Marks local minima (or regional minima)
- Maxima Detects local maxima

- Minima Detects local minima
- $\bullet \ {\tt MorphologicalGradientMagnitude} \ \ {\tt Morphological\ edge\ detector}$
- MorphologicalRange Morphological edge detector
- MorphologicalReconstruction Morphological filter
- MorphologicalSmoothing Morphological smoothing filter
- MorphologicalThreshold Morphological smoothing filter
- MultiScaleMorphologicalGradient Morphological edge detector
- Opening Morphological opening operation
- PathOpening Morphological filter
- SeededWatershed Morphological segmentation
- Tophat Morphological high-pass filter
- UpperEnvelope Upper envelope transform (a flooding and an algebraic closing)
- Watershed Morphological segmentation

1.3.11 Point Operations

- Clip Point operation
- Compare Compare grey values in two images
- ContrastStretch Point operation
- Equal Compare grey values in two images
- ErfClip Point Operation
- Greater Compare grey values in two images
- HysteresisThreshold Point Operation
- IsodataThreshold Point operation
- Lesser Compare grey values in two images
- NotEqual Compare grey values in two images
- NotGreater Compare grey values in two images
- NotLesser Compare grey values in two images
- NotZero Point Operation
- RangeThreshold Point Operation

- Select Configurable selection function
- SelectValue Point Operation
- Threshold Point Operation

1.3.12 Transforms

- \bullet Fourier Transform Computes the Fourier transform
- HartleyTransform Computes the Hartley transform

1.3.13 Distance Transforms

- EuclideanDistanceTransform Euclidean distance transform
- GreyWeightedDistanceTransform Grey weighted distance transform
- GrowRegionsWeighted Grow labelled regions using grey-weighted distances
- VectorDistanceTransform Euclidean vector distance transform

1.4 Application Functions

1.4.1 Smoothing

- Closing Morphological closing operation
- Gauss Gaussian Filter
- GaussFT Gaussian Filter through the Fourier Domain
- Kuwahara Edge perserving smoothing filter
- KuwaharaImproved Edge perserving smoothing filter
- MedianFilter Non-linear smoothing filter
- MorphologicalSmoothing Morphological smoothing filter
- MorphologicalThreshold Morphological smoothing filter
- Opening Morphological opening operation
- PercentileFilter Rank-order filter
- Uniform Uniform filter
- Upper Envelope Upper envelope transform (a flooding and an algebraic closing)

1.4.2 Sharpening

• Sharpen - Enhance an image

1.4.3 Line and Edge Detection

- DanielsonLineDetector Line detector
- GradientMagnitude Derivative filter
- Laplace Second order derivative filter
- Lee Morphological edge detector
- MorphologicalGradientMagnitude Morphological edge detector
- MorphologicalRange Morphological edge detector
- MultiScaleMorphologicalGradient Morphological edge detector

1.4.4 Extrema Detection

- LocalMinima Marks local minima (or regional minima)
- Maxima Detects local maxima
- Minima Detects local minima
- SubpixelLocation Gets coordinates of an extremum with sub-pixel precision
- SubpixelMaxima Gets coordinates of local maxima with sub-pixel precision
- SubpixelMinima Gets coordinates of local minima with sub-pixel precision

1.4.5 Object Generation

- CityBlockDistanceToPoint Distance generation function
- EllipticDistanceToPoint Distance generation function
- EuclideanDistanceToPoint Distance generation function
- FTBox Generates the Fourier transform of a box
- FTCross Generates the Fourier transform of a cross
- FTCube Generates the Fourier transform of a cube
- FTEllipsoid Generates Fourier transform of a ellipsoid
- FTGaussian Generates the Fourier transform of a Gaussian

- FTSphere Generated Fourier transform of a sphere
- IncoherentOTF Generates an incoherent OTF
- IncoherentPSF Generates an incoherent PSF
- PaintBox Paint a box
- PaintDiamond Paint a diamond-shaped object
- PaintEllipsoid Paint an ellipsoid
- TestObjectAddNoise TestObject generation function
- TestObjectBlur TestObject generation function
- TestObjectCreate TestObject generation function
- TestObjectModulate TestObject generation function

1.4.6 Noise Generation

- BinaryNoise Generates an image disturbed by binary noise
- BinaryRandomVariable Binary random variable generator
- GaussianNoise Generate an image disturbed by Gaussian noise
- GaussianRandomVariable Gaussian random variable generator
- PoissonNoise Generate an image disturbed by Poisson noise
- PoissonRandomVariable Poisson random variable generator
- RandomSeed Initialise random number generator
- RandomSeedVector Initialise random number generator
- Random Variable Random number generator
- UniformNoise Generate an image disturbed by uniform noise
- UniformRandomVariable Uniform random variable generator

1.4.7 Image Restoration

AdaptiveBanana

Performs Gaussian filtering steered by paramter images

SYNOPSIS

```
#include "dip_adaptive.h"
dip_Error DIP_TPI_FUNC(dip_AdaptiveBanana)( in, out, para_images, curv_image,
filterSize, order, truncation )
```

DATA TYPES

sfloat

FUNCTION

This function performs Gaussian filtering steerd by the information stored in the parameter images (local orientation) and in the curvature image. The meaning of the parameter images depends on the dimensionality of the input image. Up to now only 2 and 3D images are supported for adaptive filtering. If the input image is not of type **float** it is converted to that type.

para_images: ImageArray containing orientation images.

2D: angle of the orientation.

3D: polar coordinate phi, theta for intrinsic 1D structures polar coordinates of two orientations for intrinsic 2D structures.

filterSize: Array containing the sigmas of the derivatives.

For intrinsic 1D structures, the first value is along the contour, the second perpendicular to it.

For intrinsic 2D structures, the first two are in the plane, whereas the other is perpendicular to them. If a value is zero no convolution is done is this direction.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|----------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| dip_Image | out | Output image |
| dip_ImageArray | para_images | Parameter images |
| $\mathtt{dip}_{-}\mathtt{Image}$ | curv | Curvature image |
| dip_FloatArray | filterSize | Size of the filter |
| dip_IntegerArray | order | Order of the Gaussian derivative |
| dip_int | truncation | Truncation of the Gaussian |

Add

arithmetic function

SYNOPSIS

dip_Error dip_Add (in1, in2, out)

DATA TYPES

binary, integer, float, complex

FUNCTION

This function computes $\mathtt{out} = \mathtt{in1} + \mathtt{in2}$ on a pixel by pixel basis. The data types of the $\mathtt{in1}$ and $\mathtt{in2}$ image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

And

logic operation

SYNOPSIS

dip_Error dip_And (in1, in2, out)

DATA TYPES

binary, integer

FUNCTION

The function And performs the logic AND operation between the corresponding pixels in in1 and in2, and stores the result in out.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|---------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First binary input image |
| $dip_{-}Image$ | in2 | Second binary input image |

AreaOpening

Morphological filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_AreaOpening ( grey, mask, out, filtersize, connectivity,
closing )
```

DATA TYPES

integer, float

FUNCTION

The image grey will be filtered to remove local maxima (closing is DIP_FALSE) or local minima (closing is DIP_TRUE) with an area smaller than filtersize (in pixels).

Theoretically, the area opening can be written as the supremum of all the openings with each of the possible compact structuring elements of filtersize pixels. The connectivity parameter indicates which shapes are considered compact (i.e. all pixels are connected). See The connectivity parameter for more information.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|---|
| ${\tt dip_Image}$ | grey | Grey-value input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask | Mask image for ROI processing |
| dip_Image | out | Output image |
| dip_int | filtersize | Size of structuring element |
| dip_int | connectivity | Connectivity |
| dip_Boolean | closing | DIP_FALSE for area opening, DIP_TRUE for area closing |

BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

ArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_ArrayNew (array, size, elementSize, resources)

FUNCTION

This functions allocates the size elements of a dip_Array and sets the size of the array to size. The size of each element is determined by elementSize.

ARGUMENTS

| Data type | Name | Description |
|---------------|-------------|--|
| dip_Array * | array | Array |
| dip_int | size | Size |
| dip_int | elementSize | ElementSize |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

Asin

trigonometric function

SYNOPSIS

dip_Error dip_Asin (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the arc sine of the input image values.

ARGUMENTS

| Data type | Name | Description |
|--------------------|------|-------------|
| ${\tt dip_Image}$ | in | Input |
| dip_Image | out | Output |

SEE ALSO

Sin, Cos, Tan, Acos, Atan, Atan2, Sinh, Cosh, Tanh

Atan

trigonometric function

SYNOPSIS

dip_Error dip_Atan (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the arc tangent of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

Sin, Cos, Tan, Asin, Acos, Atan2, Sinh, Cosh, Tanh

Atan2

arithmetic function

SYNOPSIS

dip_Error dip_Atan2 (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function computes out = atan2(in1, in2) on a pixel by pixel basis. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input |
| $dip_{-}Image$ | in2 | Second input |
| dip_Image | out | Output |

SEE ALSO

AttenuationCorrection

Attenuation correction algorithm

SYNOPSIS

#include "dip_microscopy.h"

dip_Error dip_AttenuationCorrection (in, out, fAttenuation, bAttenuation, background, threshold, NA, refIndex, ratio, method)

DATA TYPES

binary, integer, float

FUNCTION

This function implements an attenuation correction using three different recursive attenuation correction algorithms. The RAC-DET algorithm is the most accurate one, since it takes both forward and backward attenuation into account. It is however considerably slower that the RAC-LT2 and RAC-LT1 algorithms which take only forward attenuation into account. These last two algorithms assume a constant attenuation (background) for pixels with an intensity lower than the threshold.

ARGUMENTS

| Data type | Name | Description |
|----------------------------|--------------|-------------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_float | fAttenuation | Forward attenuation factor |
| dip_float | bAttenuation | Backward attenuation factor |
| dip_float | background | Background attenuation factor |
| dip_float | threshold | Background threshold |
| dip_float | NA | Numerical aperture |
| dip_float | refIndex | Refractive index |
| dip_float | ratio | Z/X sampling ratio |
| dipf_AttenuationCorrection | method | Correction method |

The dipf_AttenuationCorrection enumaration consists of the following flags:

| Name | Description |
|-------------------------|--|
| DIP_ATTENUATION_RAC_LT2 | Recursive Attenuation Correction algorithm using two Light |
| | Cone convolutions |
| DIP_ATTENUATION_RAC_LT1 | Recursive Attenuation Correction algorithm using one Light |
| | Cone convolution |
| DIP_ATTENUATION_RAC_DET | Recursive Attenuation Correction algorithm using |
| | Directional Extinction Tracking |

BiasedSigma

Adaptive edge sharpening & contrast enhancing filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_BiasedSigma ( in, out, se, boundary, param, shape, sigma,
outputCount )
```

DATA TYPES

integer, float

FUNCTION

The Biased Sigma filter is an adaptive edge sharpening and contrast enhancing filter. Its operation differs from the Sigma filter by separating the pixels with intensities higher than the pixel being filtered, from the pixels with lower intensities. The output for this pixel is the average closest in value to this pixel. If outputCount is DIP_TRUE, the output values represent the number of pixels over which the average has been calculated. When threshold is DIP_TRUE, the pixel intensities are thresholded at +/- 2 sigma, when it is set to DIP_FALSE, the intensities are weighted with the Gaussian difference with the intensity of the center pixel.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-------------|-------------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_Image | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |
| dip_float | sigma | Sigma |
| dip_Boolean | outputCount | Output the Count |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

BinaryClosing

Binary morphological closing operation

SYNOPSIS

```
#include "dip_binary.h"
dip_Error dip_BinaryClosing ( in, out, connectivity, iterations, edge )
```

DATA TYPES

binary

FUNCTION

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP_TRUE) or as background (DIP_FALSE). Additionally, you can set it to -1 for special handling: DIP_FALSE for the dilation, DIP_TRUE for the erosion; this avoids the border effect you can get in the corners of the image in some cases.

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations.

ARGUMENTS

| Data type | Name | Description |
|---|--------------|----------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | out | Output |
| dip_int | connectivity | Connectivity |
| dip_int | iterations | Iterations |
| dip_int | edge | Edge condition |

KNOWN BUGS

This function is only implemented for images with a dimension up to three.

BinaryDilation

Binary morphological dilation operation

SYNOPSIS

```
#include "dip_binary.h"
dip_Error dip_BinaryDilation ( in, out, connectivity, iterations, edge )
```

DATA TYPES

binary

FUNCTION

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP_TRUE) or as background (DIP_FALSE).

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|----------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_int | connectivity | Connectivity |
| dip_int | iterations | Iterations |
| dip_Boolean | edge | Edge pixels on |

KNOWN BUGS

This function is only implemented for images with a dimension up to three.

BinaryImageToPixelTable

Convert a binary image to a pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_BinaryImageToPixelTable ( im, table, resources )
```

DATA TYPES

binary

FUNCTION

This functions converts a binary image to a newly allocated pixel table table.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | im | Binary image |
| dip_PixelTable * | table | Pixel table |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

BinaryNoise

Generates an image disturbed by binary noise

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_BinaryNoise ( in, out, p10, p01, random )
```

DATA TYPES

binary

FUNCTION

Generate an image disturbed by binary noise. See BinaryRandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description |
|--------------|--------|---|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_float | p10 | Probability of a one to zero transition |
| dip_float | p01 | Probability of a zero to one transition |
| dip_Random * | random | Pointer to a random value structure |

EXAMPLE

Get a binary noise disturbed image as follows:

```
dip_Image in, out;
dip_float p10, p01;
dip_Random random;

p10 = 0.1;
p01 = 0.2;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_BinaryNoise( in, out, p10, p01, &random ));
```

BinaryPropagation

75

Morphological propagation of binary objects

SYNOPSIS

```
#include "dip_binary.h"
dip_Error dip_BinaryPropagation ( seed, mask, out, connectivity, iterations, edge )
```

DATA TYPES

binary

FUNCTION

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP_TRUE) or as background (DIP_FALSE).

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations, and section 10.3, "Segmentation", for applications of binary propagation.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------------|----------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | seed | Input seed |
| dip_Image | mask | Input mask |
| dip_Image | out | Output |
| dip_int | connectivity | Connectivity |
| dip_int | iterations (0) | Iterations |
| dip_Boolean | edge | Edge condition |

KNOWN BUGS

This function is only implemented for images with a dimension up to three.

BinaryRandomVariable

Binary random variable generator

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_BinaryRandomVariable ( random, input, p10, p01, output )
```

FUNCTION

The binary random variable is generated by altering the input value, if the value of a generated random variable is higher than the p10 probability, if input is DIP_TRUE, or higher than p01 otherwise.

See RandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description |
|--------------|--------|---|
| dip_Random * | random | Pointer to a random value structure |
| dip_Boolean | input | Input |
| dip_float | p10 | Probability of a one to zero transition |
| dip_float | p01 | Probability of a zero to one transition |

EXAMPLE

Get a binary random variable as follows:

```
dip_Random random;
dip_float p10, p01, value;

p10 = 0.1;
p01 = 0.2;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_BinaryRandomVariable( &random, 1, p10, p01, &value ));
```

BooleanArrayCopy

Copy an array

SYNOPSIS

dip_Error dip_BooleanArrayCopy (dest, src, resources)

FUNCTION

This function copies the boolean array src to dest. The array dest is created by this function as well.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_BooleanArray * | dest | Destination array |
| dip_BooleanArray | src | Source array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

BooleanArrayFind

Find value in array

SYNOPSIS

dip_Error dip_BooleanArrayFind (array, value, index, found)

FUNCTION

Finds a value in an array and "returns" its index in the array. If found is zero, BooleanArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP_FALSE if value is not found).

ARGUMENTS

| Data type | Name | Description |
|------------------|-------|--------------------------|
| dip_BooleanArray | array | Array to find value in |
| dip_Boolean | value | Value to find |
| dip_int * | index | Index of the found value |
| dip_Boolean * | found | Value found or not |

SEE ALSO

BooleanArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_BooleanArrayNew (array, size, value, resources)

FUNCTION

This function allocates the size elements of a dip_BooleanArray and sets the size of the array to size. Each array element is initialized with value.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_BooleanArray * | array | Array |
| dip_int | size | Size |
| dip_Boolean | value | Initial value |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

BoundaryArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_BoundaryArrayNew (array, size, value, resources)

FUNCTION

This function allocates the size elements of a dip_BoundaryArray and sets the size of the array to size. Each array element is initialized with value.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-----------|--|
| dip_BoundaryArray * | array | Boundary conditions |
| dip_int | size | Size |
| dip_Boundary | value | Initial value |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

Canny

Edge detector

SYNOPSIS

```
#include "dip_detection.h"
dip_Error dip_Canny ( in, out, sigma, upper, lower )
```

DATA TYPES

Input is integer or float; output is **binary**.

FUNCTION

The Canny edge detector finds the ridges in the gradient magnitude, which correspond to the edges in the image. The gradient magnitude (see GradientMagnitude) is computed using Gaussian derivatives, with a sigma of sigma in both dimensions. The found ridges are pruned to remove the less salient edges. A threshold t1 is computed so that the 1-upper fraction of pixels with the highest gradient magnitude are kept. A second threshold, t2 = t1*lower, is selected that determines the minimal gradient magnitude expected of an edge. All edge pixels that exceed t2, and are in the same connected region as at least one pixel that exceeds t1, are selected as the output of this function (see HysteresisThreshold).

ARGUMENTS

| Data type | Name | Description |
|---|-------|---|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | out | Output |
| dip_float | sigma | Sigma parameter for Gaussian derivatives |
| dip_float | lower | Lower threshold, as a fraction of upper threshold |
| dip_float | upper | Percentile used to compute upper threshold |

LIMITATIONS

This function only works on 2D images.

DIPlib function reference

Ceil

Arithmetic function

SYNOPSIS

dip_Error dip_Ceil (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the ceil of the input image values, and outputs a signed integer typed image.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

${\tt ChainCodeArrayFree}$

Chain code array deallocation

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeArrayFree ( array )
```

FUNCTION

This function frees *array, and sets array to zero.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|------|-----------------------------|
| dip_ChainCodeArray * arra | | Pointer to chain code array |

SEE ALSO

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeArrayNew}$

${\tt ChainCodeArrayNew}$

Chain code array allocation

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeArrayNew ( array, size, resources )
```

FUNCTION

This function allocates the size elements of a dip_ChainCodeArrayNew and sets the size of the array to size.

ARGUMENTS

| Data type | Name | Description |
|----------------------|-----------|--|
| dip_ChainCodeArray * | array | Receives pointer to allocated structure |
| dip_int | size | Number of chains to allocate space for |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeArrayFree}$

ChainCodeFree

Chain code object deallocation

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeFree ( chaincode )
```

FUNCTION

Deallocates the chaincode object created by ChainCodeNew, and sets the pointer to zero.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-----------|-----------------------|
| dip_ChainCode * | chaincode | Pointer to chain code |

SEE ALSO

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeArrayNew}, {\tt ChainCodeArrayFree}$

ChainCodeGetChains

Chain code access function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetChains ( chaincode, chain )
```

FUNCTION

Returns a pointer to the first element of the chain. Each chain element contains a pointer to the next element. The last element has a NULL pointer. ChainCodeGetSize returns the number of elements in the chain. See ChainCodeNew for more information.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--|
| dip_ChainCode | chaincode | Chain code |
| dip_Chain ** | chain | Receives the pointer to the first element in the chain |

SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize, ChainCodeGetStart, ChainCodeGetLabel, ChainCodeGetConnectivity

ChainCodeGetConnectivity

Chain code access function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetConnectivity ( chaincode, connectivity )
```

FUNCTION

Returns the connectivity used when extracting the boundary described in chaincode. connectivity==1 indicates 4-connected neighbours, and the code uses integers 0 through 3. connectivity==2 indicates 8-connected neighbours, and the code uses values 0 through 7. See The connectivity parameter.

ARGUMENTS

| Data type | Name | Description |
|---------------|--------------|--|
| dip_ChainCode | chaincode | Chain code |
| dip_int * | connectivity | Receives the connectivity value in chaincode |

SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize,
ChainCodeGetChains, ChainCodeGetStart, ChainCodeGetLabel

ChainCodeGetFeret

Chain code measurement function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetFeret ( chaincode, stepSize, feret )
```

FUNCTION

This function measures the longest and shortest projections of the object encoded by chaincode. The chain code is rotated in stepSize degree intervals and the length of the projection on the x and y axes is computed for each orientation. The sizes of maximum and minimum projections, as well as the rotation at which they were obtained, are returned in the feret structure, which contains the following elements:

| Data type | Name | Description |
|-----------|------------------|--|
| dip_float | maxDiameter | The widest projection of the object |
| dip_float | minDiameter | The narrowest projection of the object |
| dip_float | maxPerpendicular | The width of the projection perpendicular to |
| | | minDiameter |
| dip_float | maxAngle | The angle of the projection for maxDiameter |
| dip_float | minAngle | The angle of the projection for minDiameter |

ChainCodeGetFeret is the function used by Measure for the FeatureFeret measurement.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|---------------------------|
| dip_ChainCode | chaincode | Input chain code |
| dip_float | stepSize | The step size, in degrees |
| dip_Feret * | feret | Output measurement |

CREDITS

The original code on which the current implementation is based, was donated by Gerie van der Heijden.

SEE ALSO

ChainCodeGetLabel

Chain code access function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetLabel ( chaincode, label )
```

FUNCTION

Returns the label ID of the object whose boundary is described by chaincode.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|------------------------------------|
| dip_ChainCode | chaincode | Chain code |
| dip_int * | label | Receives the label ID in chaincode |

SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize,
ChainCodeGetChains, ChainCodeGetStart, ChainCodeGetConnectivity

ChainCodeGetLength

Chain code measurement function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetLength ( chaincode, length )
```

FUNCTION

Computes the length of the boundary encoded by chaincode. See FeaturePerimeter for a description of the algorithm. ChainCodeGetLength is the function used by Measure for the FeaturePerimeter measurement.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--------------------|
| dip_ChainCode | chaincode | Input chain code |
| dip_float * | length | Output measurement |

SEE ALSO

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeGetLongestRun}, {\tt ChainCodeGetFeret}, {\tt ChainCodeGetRadius}$

${\tt ChainCodeGetLongestRun}$

Chain code measurement function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetLongestRun ( chaincode, longestRun )
```

FUNCTION

Returns the number of pixels in the longest run of identical codes in chaincode. This represents the longest straight section of the boundary. ChainCodeGetLongestRun is the function used by Measure for the FeatureLongestChaincodeRun measurement.

ARGUMENTS

| Data type | Name | Description |
|---------------|------------|--|
| dip_ChainCode | chaincode | Input chain code |
| dip_int * | longestRun | Receives the pixel count for the longest run |

SEE ALSO

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeGetLength}, {\tt ChainCodeGetFeret}, {\tt ChainCodeGetRadius}$

ChainCodeGetRadius

Chain code measurement function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetRadius ( chaincode, radius )
```

FUNCTION

This function computes statistics on the radius of an object. The centre of gravity of the object's border pixels is used as the centre of the object. The distance from each border pixel to this centre is is computed. The maximum, minimum, mean and variance of these distances are returned in the radius structure, which contains the following elements:

| Data type | Name | Description |
|-----------|------|---------------------------|
| dip_float | max | Maximum object radius |
| dip_float | mean | Mean object radius |
| dip_float | min | Minimum object radius |
| dip_float | var | Variance of object radius |

ChainCodeGetRadius is the function used by Measure for the FeatureRadius measurement.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|-----------|--------------------|
| $\mathtt{dip_ChainCode}$ | chaincode | Input chain code |
| dip_CCRadius * | radius | Output measurement |

SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetLength,
ChainCodeGetLongestRun, ChainCodeGetFeret

ChainCodeGetSize

Chain code access function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetSize ( chaincode, number )
```

FUNCTION

Returns the number of elements in the chain code.

Note: this is not a correct measure for the object's perimeter, use <code>ChainCodeGetLength</code> instead.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|---|
| dip_ChainCode | chaincode | Chain code |
| dip_int * | number | Receives the number of elements in the chain. |

SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetChains,
ChainCodeGetStart, ChainCodeGetLabel, ChainCodeGetConnectivity

ChainCodeGetStart

Chain code access function

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetStart ( chaincode, startX, startY )
```

FUNCTION

Returns the start coordinates of the chain.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--|
| dip_ChainCode | chaincode | Chain code |
| dip_int * | startX | Receives the start x-coordinate in chaincode |
| dip_int * | startY | Receives the start y-coordinate in chaincode |

SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize,
ChainCodeGetChains, ChainCodeGetLabel, ChainCodeGetConnectivity

ChainCodeNew

Chain code object allocation

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeNew ( chaincode, resources )
```

FUNCTION

Allocates an object of type dip_ChainCode. However, since it's fields are private and currently there exist only read access functions, it is of little use creating such an object.

| A dip_ChainCode object stores the following da | A d | ode o | biect | stores | the | following | data: |
|--|-----|-------|-------|--------|-----|-----------|-------|
|--|-----|-------|-------|--------|-----|-----------|-------|

| Data type | Name | Description |
|-------------|---|---|
| dip_int | startX | Start coordinates for chain, ChainCodeGetStart |
| dip_int | startY | Start coordinates for chain, ChainCodeGetStart |
| dip_int | label | Label ID of object, ChainCodeGetLabel |
| dip_int | connectivity Connectivity of chain, ChainCodeGetConnect | |
| dip_int | number | Number of elements in chain, ChainCodeGetSize |
| dip_Chain * | chain | Pointer to first element in chain, ChainCodeGetChains |

The dip_Chain structure has the following elements:

| Data type | Name | Description | |
|-------------|--------|--|--|
| dip_uint8 | code | Direction of step taken from previous to this pixel (Freeman | |
| | | code) | |
| dip_Boolean | border | Pixel is on the border | |
| dip_Chain * | next | Pointer to the next element in the chain | |

The chain parameter points to the first dip_Chain object in the chain, which points to the next through its next value. The last element in the chain has a NULL pointer.

Each chain element contains the code value (between 0 and 3 or between 0 and 7, depending on the connectivity) as well as a border value, which indicates whether the pixel is on the edge of the image or not. The border value is important because it indicates that the object is cut by the imaging window and needs to be treated differently.

The chain code for an object always has as many elements as the object has border pixels.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-----------|--|
| dip_ChainCode * | chaincode | Receives pointer to allocated structure |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

ChangeDataType

101

Change the data type of an image

SYNOPSIS

dip_Error dip_ChangeDataType(example, target, dataType)

FUNCTION

Inherit all properties of the input image except the data type. The data type is explicitly specified through dataType. When dataType is zero, the data type of the output image is not modified. The example image may be either "raw" or "forged".

ARGUMENTS

| Data type | Name | Description | |
|--------------------|----------|------------------|--|
| ${\tt dip_Image}$ | example | An example image | |
| dip_Image | target | The target image | |
| dip_DataType | dataType | The data type | |

SEE ALSO

DIPlib's data types

ImageCopyProperties, ImageAssimilate, ChangeToOd

ChangeDimensions

Changes the order of the dimensions in an image

SYNOPSIS

dip_Error dip_ChangeDimensions(image, neworder)

FUNCTION

Re-orders the dimensions in an image, optionally removing singleton dimensions (those dimensions with size 1), without copying the data. neworder is a list of the dimension numbers in the new order, for example (2,1,3) will swap the first two dimensions. Setting neworder to 0 removes all singleton dimensions without altering the order. This is useful, for example, after calling a function such as Maximum to compute a maximum projection over one dimension. The output image keeps the dimensionality of the input image, and thus has a singleton dimension.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|---------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | image | The image to modify |
| dip_IntegerArray | neworder | The new order of the dimensions |

SEE ALSO

The image structure

ImageGetDimensions, ImageSetDimensions, ImageGetStride

DIP*lib* function reference

ChangeTo0d

Make an image zero dimensional

SYNOPSIS

dip_Error dip_ChangeToOd(example, target, dataType)

FUNCTION

Inherit all properties of the input image except the data type and the dimensionality. The data type is explicitly specified through dataType. When dataType is zero, the data type of the output image is not modified. The dimensionality is set to zero. The example image may be either "raw" or "forged".

ARGUMENTS

| Data type | Name | Description | |
|----------------------------------|----------|--|--|
| ${\tt dip_Image}$ | example | An example image | |
| $\mathtt{dip}_{-}\mathtt{Image}$ | target | The target image | |
| dip_DataType | dataType | The data type. See DIPlib's data types | |

SEE ALSO

ChordLength

Compute the chord lengths of the different phases

SYNOPSIS

```
#include "dip_analysis.h"
dip_Error dip_ChordLength ( object, mask, dist, probes, length, sampling )
```

DATA TYPES

binary, integer

FUNCTION

This function computes the chord lengths of the different phases in object. If object is a binary image, the image is a regarded as a two phase image. In case object is of the integer type, the image is regarded as a labeled image, with each integer value encoding a phase. Optionally a mask image can be provided to select which pixels in object should be used to compute the chord lengths. The probes variable specifies how many random point pairs should be drawn to compute the lengths. Length specifies the maximum correlation length. The correlation function can be computed using a random (DIP_CORRELATION_ESTIMATOR_RANDOM) or grid method

(DIP_CORRELATION_ESTIMATOR_GRID), as specified by sampling.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|----------|----------------------|
| dip_Image | object | Object image |
| dip_Image | mask | Mask image |
| dip_Distribution | dist | Ouput distribution |
| dip_int | probes | Number of probes |
| dip_int | length | Maximum chord length |
| dipf_CorrelationEstimator | sampling | Samplings method |

CityBlockDistanceToPoint

Distance generation function

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_CityBlockDistanceToPoint ( output, origin, scale )
```

DATA TYPES

Output: sfloat

FUNCTION

Computes the cityblock distance of each pixel in the output image to a point at origin. The coordinates of origin may lie outside the image. The scale parameter may be used to specify the relative distance between pixels in each dimension.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------|--|
| ${\tt dip_Image}$ | output | Output Image |
| dip_FloatArray | origin | Origin |
| dip_FloatArray | scale | Relative scale of the pixel distances for each dimension |

SEE ALSO

EllipticDistanceToPoint, EuclideanDistanceToPoint

Clip

Point operation

SYNOPSIS

```
#include "dip_point.h"
dip_Error dip_Clip ( in, out, clipLow, clipHigh, clipFlag )
```

DATA TYPES

integer, float

FUNCTION

Clips in at either the minimum value clipLow of the maximum value clipHigh or both. If the flag DIP_CLIP_THRESHOLD_AND_RANGE is specified, the clip bound are defined by clipLow +/- clipHigh/2.

ARGUMENTS

| Data type | Name | Description |
|---|----------|-------------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_float | clipLow | Lower clip bound value |
| dip_float | clipHigh | Higher clip bound value |
| dipf_Clip | clipFlag | Clip flag |

The following dipf_Clip flags are defined:

| Name | Description |
|------------------------------|---|
| DIP_CLIP_BOTH | clip both the lower and upper bound |
| DIP_CLIP_LOW | clip lower bound only |
| DIP_CLIP_HIGH | clip upper bound only |
| DIP_CLIP_THRESHOLD_AND_RANGE | use clipLow and clipHigh as threshold and range |
| | value |
| DIP_CLIP_LOW_AND_HIGH_BOUNDS | same as DIP_CLIP_BOTH |

SEE ALSO

Threshold, RangeThreshold, ErfClip, ContrastStretch

Closing

107

Morphological closing operation

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Closing ( in, out, se, boundary, param, shape )
```

DATA TYPES

integer, float, binary

FUNCTION

Grey-value closing with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

Colour2Gray

109

Convert ND image with colour information to a (n-1)D grayvalue image (in diplO)

SYNOPSIS

```
#include "dipio_tools.h"
dip_Error dipio_Colour2Gray ( in, out, photometric )
```

FUNCTION

This function converts a colour image, as read by ImageReadColour, to a grayvalue intensity image. in is expected to contain the colour information along the last axis. out will be a scalar image with one less dimension than the input.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|----------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |

The enumerator ${\tt dipio_PhotometricInterpretation}$ contains the following constants:

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

Most file formats support only some of these.

KNOWN BUGS

Some colourspaces are not converted correctly. R'G'B' (DIPIO_PHM_RGB_NONLINEAR), is treated like RGB. From a CIE Lab (DIPIO_PHM_CIELAB) or Luv (DIPIO_PHM_CIELUV) the luminosity channel is extracted, which is also a non-linear conversion away from the intensity. From HCV (DIPIO_PHM_HCV) and HSV (DIPIO_PHM_HSV) the value channel is extracted, which again is a non-linear conversion away from the intensity. CMYK (DIPIO_PHM_CMYK) and CMY (DIPIO_PHM_CMY) conversion is not implemented. Specifying these values will result in an error.

Compare

Compare grey values in two images

SYNOPSIS

dip_Error dip_Compare (in1, in2, out, selector)

DATA TYPES

binary, integer, float

FUNCTION

This function can perform various pixel-by-pixel comparisons (smaller, smaller- equal, equal, not equal, greater-equal, greater) between in1 ans in2. out contains the binary result. This is implemented with a call to Select whose in3 and in4 are set to binary true and false, respectively.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to the functionality of Threshold, but with more options.

ARGUMENTS

| Data type | Name | Description |
|---|----------|------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | out | Output |
| dipf_Select | selector | Select flag |
| Name | | Description |
| DIP_SELECT_LESSER | | <, Lesser than |
| DIP_SELECT_LESSER_EQUAL | | <=, Lesser or equal |
| DIP_SELECT_NOT_EQUAL | | !=, Unequal |
| DIP_SELECT_EQUAL | | ==, Equal |
| DIP_SELECT_GREATER_EQUAL | | L >=, Greater or equal |
| DIP_SELECT_GREATER | | >, Greater |

SEE ALSO

Select, Threshold, Equal, Greater, Lesser, NotEqual, NotGreater, NotLesser, SelectValue, NotZero

${\tt ComplexArrayCopy}$

Copy an array

SYNOPSIS

dip_Error dip_ComplexArrayCopy (dest, src, resources)

FUNCTION

This function copies the complex array src to dest. The array dest is created by this function as well.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_ComplexArray * | dest | Destination array |
| dip_ComplexArray | src | Source array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

ComplexArrayFind

Find value in array

SYNOPSIS

dip_Error dip_ComplexArrayFind (array, value, index, found)

FUNCTION

Finds a value in an array and "returns" its index in the array. If found is zero, ComplexArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP_FALSE if value is not found).

ARGUMENTS

| Data type | Name | Description |
|------------------|-------|--------------------------|
| dip_ComplexArray | array | Array to find value in |
| dip_complex | value | Value to find |
| dip_int * | index | Index of the found value |
| dip_Boolean * | found | Value found or not |

SEE ALSO

ComplexArrayNew, ComplexArrayFree, ComplexArrayCopy, ComplexArrayFind IntegerArrayFind, FloatArrayFind, ComplexArrayFind, DataTypeArrayFind, BooleanArrayFind, VoidPointerArrayFind

${\tt ComplexArrayFree}$

Array free function

SYNOPSIS

dip_Error dip_ComplexArrayFree (array)

FUNCTION

This function frees *array, and sets array to zero.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-------|-------------|
| dip_ComplexArray * | array | Array |

SEE ALSO

 ${\tt ComplexArrayNew, ComplexArrayFree, ComplexArrayCopy, ComplexArrayFind}$

ArrayFree, IntegerArrayFree, FloatArrayFree, ComplexArrayFree,

ComplexArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_ComplexArrayNew (array, size, value, resources)

FUNCTION

This function allocates the size elements of a dip_ComplexArray and sets the size of the array to size. Each array element is initialized with value.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_ComplexArray * | array | Array |
| dip_int | size | Size |
| dip_complex | value | Initial value |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

ContrastStretch

Point operation

SYNOPSIS

#include "dip_point.h"

dip_Error dip_ContrastStretch (in, out, lowerBound, upperBound, outMaximum, outMinimum, method, sigmoidSlope, sigmoidPoint, maxDecade)

DATA TYPES

integer, float

FUNCTION

ContrastStretch stretches the pixel values of the input image. Pixel values higher or equal to UpperBound are stretched to the OutMaximum value. A similar thing holds for LowerBound and OutMinimum. Method determines how pixel values are stretched. SigmoidSlope and SigmoidPoint are used by the DIP_CST_SIGMOID method. MaxDecade determines the maximum number of decades the method DIP_CST_DECADE will stretch (values lower than MaxDecade will be set to zero).

ARGUMENTS

| Data type | Name | Description |
|----------------------|--------------|----------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_float | lowerBound | LowerBound (%) |
| dip_float | upperBound | UpperBound (%) |
| dip_float | outMax | OutMaximum |
| dip_float | outMin | OutMinimum |
| dipf_ContrastStretch | method | Method |
| dip_float | sigmoidSlope | SigmoidSlope |
| dip_float | sigmoidPoint | SigmoidPoint |
| dip_float | maxDecade | MaxDecade |

The following dipf_ContrastStretch flags are defined:

| Name | Description |
|----------------------------|---|
| DIP_CST_LINEAR | linear contrast stretch |
| DIP_CST_SIGNED_LINEAR | linear stretch with zero at fixed value |
| DIP_CST_LOGARITHMIC | logarithmic contrast stretch |
| DIP_CST_SIGNED_LOGARITHMIC | signed logarithmic contrast stretch |
| DIP_CST_ERF | linear contrast stretch with erf clipping |
| DIP_CST_DECADE | Decade contrast stretching |
| DIP_CST_SIGMOID | Contrast stretched by sigmoid function |
| DIP_CST_CLIP | Simple clipping |
| DIP_CST_01 | Stretching of [0,1] input values |
| DIP_CST_PI | Stretching of [-Pi,Pi] input values |

In the explanaition of the different contrast stretch flags, the variables input, output, inMin, inMax, outMin and outMax are used. With input and output is meant the pixel being processed of respecitively the input and output image. inMin and inMax are the pixel values corresponding to the lowerBound and upperBound of the input image. outMin and outMax are parameters passed to the function dip_ContrastStretch.

The DIP_CST_LINEAR stretches the input in the following way:

```
scale = (outMax - outMin) / (inMax - inMin)
output = scale * (MIN(inMax, MAX(inMin, input )) - inMin) + outMin
```

The DIP_CST_SIGNED_LINEAR stretches the input in the following way:

```
max = MAX(inMax, ABS( inMin ));
scale = (outMax - outMin) / (2 * max)
offset = (outMax - outMin) / 2
output = scale * (MIN(inMax, MAX(inMin, input)) - offset) + outMin
```

The DIP_CST_LOGARITHMIC stretches the input in the following way:

```
scale = (outMax - outMin) / log( inMax - inMin + 1)
offset = inMin - 1
output = scale * log(MIN(inMax, MAX(inMin, input)) - offset) + outMin
```

The DIP_CST_SIGNED_LOGARITHMIC stretches the input in the following way:

```
max = MAX(inMax, ABS(inMin))
scale = (outMax - outMin) / (2 * log(max + 1))
offset = (outMax + outMin) / 2
output = scale * log(MIN(inMax, MAX(inMin, input)) - offset) + outMin
```

The DIP_CST_ERF stretches the input in the following way:

```
scale = (outMax - outMin) / (inMax - inMin)
```

```
threshold = (inMax + inMin) / 2
range = inMax - inMin
in = MIN(inMax, MAX(inMin, input))
out = (range / 2) * erf( SQRT_PI * (in - threshold) / range )
output = scale * (out + threshold ) + outMin
```

The DIP_CST_DECADE stretches the input in the following way:

```
inScale = inMax - inMin
outScale = outMax - outMin
in = MIN(inMax, DIP_MAX(inMin, input))
decade = log10(inScale / (in - inMin + EPSILON))
if(decade < maxDecade)
  decade -= floor(decade)
  output = outScale * (1 - decade) + outMin
else
  output = 0</pre>
```

The DIP_CST_SIGMOID stretches the input in the following way:

The DIP_CST_CLIP stretches the input in the following way:

```
output = MIN(outMax, MAX(outMin, input))
```

The DIP_CST_01 stretches the input in the following way:

```
scale = (outMax - outMin)
output = scale * input + outMin
```

The DIP_CST_01 stretches the input in the following way:

```
scale = (outMax - outMin) / 2 * Pi
output = scale * (input + Pi) + outMin
```

DIP*lib* function reference

ConvertArray

converts the data type of an array

SYNOPSIS

```
#include "dip_convert_array.h"
dip_Error DIP_TWO_FUNC(dip_ConvertArray)( in, inStride, inPlane, out,
outStride, outPlane, number )
```

FUNCTION

Converts the in array to the out array.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|-----------|--|
| void * | in | input array |
| dip_int | inStride | Stride of the input array |
| dip_int | inPlane | plane number in case in is a binary array |
| void * | out | output array |
| $\mathtt{dip}_{-}\mathtt{int}$ | outStride | Stride of the output array |
| dip_int | outPlane | plane number in case out is a binary array |
| dip_int | number | size of the arrays |

ConvertDataType

Converts the data type of an image

SYNOPSIS

dip_Error dip_ConvertDataType (in, out, dataType)

FUNCTION

Convert the data type of the input data to dataType and stores the result in out.

Conversion from a *complex* type to another (non-complex) type, is done by taking the real part.

Conversion to a *binary* type from another (non-binary) type, is done as follows; any non-zero number becomes 1, zero becomes zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|------------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_DataType | dataType | Data type. See DIPlib's data types |

DIP*lib* function reference

Convolve1d

121

Perform a 1D convolution

SYNOPSIS

```
#include "dip_linear.h"
dip_Error DIP_TPI_FUNC(dip_Convolve1d)( in, out, filter, size, filterSize, origin, flags, boundary )
```

DATA TYPES

integer, float

FUNCTION

This function performs a one-dimensional convolution of the input data with the given filter kernel. In general your filter will be centered around the origin. The origin is uniquely defined if the filter size is odd, but if the filter size is even you'll have to specify whether the origin of the filter lies to the left or the right. Words cannot possibly suffice here, so here is a small pictorial representation:

When the filter size is even, one of the flags <code>DIP_CNV_LEFT</code> or <code>DIP_CNV_RIGHT</code> must be specified. When the filter size is odd both flags are ignored. It is also possible to specify the origin of the filter directly by using the <code>DIP_CNV_USE_ORIGIN</code> flag in combination with the <code>origin</code> parameter. Again a small pictorial representation:

```
0 1 2 3 4 5 6 7 8
kernel data : x x x x x x x x x when origin = 2
```

0

when DIP_CNV_USE_ORIGIN is NOT specified origin is computed as follows:

```
filter size odd origin = (filterSize - 1) / 2
filter size even _and_
   DIP_CNV_LEFT origin = (filterSize / 2) - 1
   DIP_CNV_RIGHT origin = filterSize / 2
```

The input data is copied to a temporary buffer, after which the input data is extended according to the boundary condition specified. You can use the flags DIP_CNV_HAS_BORDER to indicate that the input data already has a border. In this case you must make sure that there are enough pixels on either side of the array:

```
on the left : ((filterSize - 1) - origin) pixels on the right: (origin) pixels
```

If DIP_CNV_HAS_BORDER is specified and in != out no auxiliary storage is used.

You must also specify the symmetry of the filter as follows:

```
odd filter size
                                        DIP_CNV_EVEN
                      a b
                               b
                            С
                                        DIP_CNV_ODD
                         b
                            c -b -a
                            c d e
                                        DIP_CNV_GENERAL
                      a b
even filter size
                                        DIP_CNV_EVEN
                        b
                                        DIP_CNV_ODD
                                        DIP_CNV_GENERAL
                      a b c d e f
```

ARGUMENTS

| Data type | Name | Description |
|------------------------|------------|---|
| void * | in | Pointer to the input data |
| void * | out | Pointer to the output data |
| void * | filter | Pointer to the filter data |
| dip_int | size | Size of the input data |
| dip_int | filterSize | Size of the filter |
| dip_int | origin | Origin of the filter. Only valid in conjunction with |
| | | DIP_CNV_USE_ORIGIN |
| ${\tt dipf_Convolve}$ | flags | A combination of the flags described above |
| dip_Boundary | boundary | One of the standard boundary conditions. See Boundary |
| | | conditions |

ConvolveFT

Fourier transform-based convolution filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_ConvolveFT ( in, psf, out, inrep, psfrep, outrep )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function convolves the in image with the point spread function psf, by multiplying their Fourier transforms. The inrep, psfrep and outrep specify whether the images are spatial images (DIP_IMAGE_REPRESENTATION_SPATIAL) or their Fourier transform. (DIP_IMAGE_REPRESENTATION_SPECTRAL).

out is cast to a real type if and only if both in and psf are real and in the spatial domain. That is, no effort is made to check for evenness of images in the Fourier domain, nor to check the values of the imaginary component of the result. To convert the output to a real-valued type, use the function ConvertDataType.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------------|--------|----------------------------|
| dip_Image | in | Input image |
| dip_Image | psf | Psf image |
| dip_Image | out | Output image |
| ${\tt dipf_ImageRepresentation}$ | inrep | Input spatial or spectral |
| ${\tt dipf_ImageRepresentation}$ | psfrep | PSF spatial or spectral |
| dipf_ImageRepresentation | outrep | Output spatial or spectral |

CoordinateArrayFree

Array free function

SYNOPSIS

dip_Error dip_CoordinateArrayFree (array)

FUNCTION

This function frees *array, and sets array to zero.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-------|-------------|
| dip_CoordinateArray * | array | Array |

SEE ALSO

CoordinateArrayNew, CoordinateArrayFree

ArrayFree, IntegerArrayFree, FloatArrayFree, ComplexArrayFree,
BoundaryArrayFree, FrameWorkProcessArrayFree, DataTypeArrayFree, ImageArrayFree,
BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

CoordinateArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_CoordinateArrayNew (array, ndims, size, resources)

FUNCTION

This function allocates the size elements of a dip_CoordinateArray and sets the size of the array to size. Each element has ndims values, to store coordinates of an ndims-dimensional image. Each array element is initialized to 0.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-----------|--|
| dip_CoordinateArray * | array | Array |
| dip_int | ndims | Dimensionality |
| dip_int | size | Size |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

CoordinateToIndex

Convert coordinate to pixel index

SYNOPSIS

```
#include "dip_coordsindx.h"
dip_Error dip_CoordinateToIndex ( coordinates, index, stride )
```

FUNCTION

This function converts a pixel coordinate to an pixel index which is specific for the image from which stride was obtained. coordinages and stride must have the same number of elements.

ARGUMENTS

| Data type | Name | Description |
|------------------|-------------|------------------------|
| dip_IntegerArray | coordinates | Coordinate array |
| dip_int * | index | Pointer to pixel index |
| dip_IntegerArray | stride | stride array |

SEE ALSO

 ${\tt IndexToCoordinate}$

Cos

trigonometric function

SYNOPSIS

dip_Error dip_Cos (in, out)

DATA TYPES

binary, integer, **float**, **complex**

FUNCTION

Computes the cosine of the input image values.

ARGUMENTS

| Data type | Name | Description |
|--------------------|------|-------------|
| ${\tt dip_Image}$ | in | Input |
| dip_Image | out | Output |

129

Cosh

trigonometric function

SYNOPSIS

dip_Error dip_Cosh (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the hyperbolic cosine of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

Sin, Cos, Tan, Asin, Acos, Atan, Atan2, Sinh, Tanh

Crop

Remove the outer parts of an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Crop ( in, out, origin, size )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Crop a part of the image. The requested part is selected by specifying its upper left corner (origin), and its size (size). If in has a different type than out, it will be converted to the type of out.

ARGUMENTS

| Data type | Name | Description |
|---|--------|--|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | in | Input Image |
| dip_Image | out | Output Image |

CrossCorrelationFT

131

Normalized cross-correlation using the Fourier Transform

SYNOPSIS

```
#include "dip_findshift.h"
dip_Error dip_CrossCorrelationFT ( in1, in2, out, in1rep, in2rep, outrep )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function calculates the cross-correlation between two images of equal size. The returned image is the cross-correlation normalized in such a way that only the phase information is of importance. This results as a very sharp peak in the spatial domain. This function performs out = (Conj(in1)*in2)/((Abs(in1))^2) in the Fourier domain. It is used by FindShift. The inrep, psfrep and outrep specify whether the images are spatial images (DIP_IMAGE_REPRESENTATION_SPATIAL) or their Fourier transform. (DIP_IMAGE_REPRESENTATION_SPECTRAL).

ARGUMENTS

| Data type | Name | Description |
|--------------------------|--------|-----------------------------|
| dip_Image | in1 | Input image |
| dip_Image | in2 | Input image |
| dip_Image | out | Output image |
| dipf_ImageRepresentation | in1rep | Input 1 spatial or spectral |
| dipf_ImageRepresentation | in2rep | Input 2 spatial or spectral |
| dipf_ImageRepresentation | outrep | Output spatial or spectral |

SEE ALSO

FindShift

CumulativeSum

statistics function

SYNOPSIS

dip_Error dip_CumulativeSum (in, mask, out, ps)

DATA TYPES

binary, integer, float, complex

FUNCTION

Calculates the cumulative sum of the pixel values over all those dimensions which are specified by ps, i.e.:

 $\operatorname{out}(x,y)=\sup_{i=0:x,j=0:y}\inf(i,j)$ when ps specifies both x and y $\operatorname{out}(x,y)=\sup_{j=0:y}\inf(x,j)$ when ps specifies only y

ARGUMENTS

| Data type | Name | Description |
|---|----------|-----------------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | in | Input |
| dip_Image | mask (0) | Mask |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_BooleanArray | ps (0) | Dimensions to project |

DanielsonLineDetector

Line detector

SYNOPSIS

```
#include "dip_orientation.h"
dip_Error dip_DanielsonLineDetector ( in, line, energy, angle, boundary,
sigma, truncation, flavour )
```

DATA TYPES

binary, integer, float

FUNCTION

The Danielson line dectector uses second derivatives to detect lines in 2D images and to estimate their orientation. See the literature reference for an in-depth information on this detector.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|------------|-----------------------------|
| dip_Image | in | Input image |
| dip_Image | line | Line image |
| dip_Image | energy | Energy image |
| dip_Image | angle | Angle image |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | sigma | Sigma of second derivatives |
| dip_float | truncation | Gauss Truncation, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative filter flavour |

DataTypeAllowed

Check whether a data type is allowed

SYNOPSIS

dip_Error dip_DataTypeAllowed(dataType, allow, allowedTypes, allowed)

FUNCTION

This function checks whether the dataType is (or is not) in the set of data types specified by allowedTypes. If allow is DIP_TRUE, the data type should be in this set. If allow is DIP_FALSE, the data type should not be in this set. If the allowed parameter is zero, the routine returns dip_errorDataTypeNotSupported if the required condition is not satisfied. If nonzero, it should point to a boolean variable. This boolean variable will be set to DIP_TRUE if the condition is satisfied, or DIP_FALSE if not.

ARGUMENTS

| Data type | Name | Description |
|------------------------|--------------|--|
| dip_DataType | dataType | The data type to check |
| dip_Boolean | allow | DIP_TRUE: check if the data type is |
| | | included. DIP_FALSE: check if the data type |
| | | is not included |
| dip_DataTypeProperties | allowedTypes | The set of data types to check against, see |
| | | DataTypeGetInfo |
| dip_Boolean * | allowed | Pointer to a boolean to store the answer, or |
| | | 0 to indicate that |
| | | $	exttt{dip_errorDataTypeNotSupported} 	ext{ should}$ |
| | | be returned if the condition is not satisfied |

DataTypeArrayCopy

Copy an array

SYNOPSIS

dip_Error dip_DataTypeArrayCopy (dest, src, resources)

FUNCTION

This function copies the data type array src to dest. The array dest is created by this function as well.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-----------|--|
| dip_DataTypeArray * | dest | Destination array |
| dip_DataTypeArray | src | Source array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

DataTypeArrayFind

Find value in array

SYNOPSIS

dip_Error dip_DataTypeArrayFind (array, value, index, found)

FUNCTION

Finds a value in an array and "returns" its index in the array. If found is zero, DataTypeArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP_FALSE if value is not found).

ARGUMENTS

| Data type | Name | Description |
|-------------------|-------|--------------------------|
| dip_DataTypeArray | array | Array to find value in |
| dip_DataType | value | Value to find |
| dip_int * | index | Index of the found value |
| dip_Boolean * | found | Value found or not |

SEE ALSO

DataTypeArrayFree

Array free function

SYNOPSIS

dip_Error dip_DataTypeArrayFree (array)

FUNCTION

This function frees *array, and sets array to zero.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-------|-------------|
| dip_DataTypeArray * | array | Array |

SEE ALSO

DataTypeArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_DataTypeArrayNew (array, size, value, resources)

FUNCTION

This function allocates the size elements of a dip_DataTypeArray and sets the size of the array to size. Each array element is initialized with value.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-----------|--|
| dip_DataTypeArray * | array | Array |
| dip_int | size | Size |
| dip_DataType | value | Initial value |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

DataTypeGetInfo

Get information about a data type

SYNOPSIS

dip_Error dip_DataTypeGetInfo(dataType, info, whatInfo)

ARGUMENTS

| Data type | Name | Description |
|----------------------|----------|---|
| dip_DataType | dataType | The data type to get information about |
| void * | info | Pointer to a variable to put the information in |
| dipf_DataTypeGetInfo | whatInfo | What information should be returned |

FUNCTION

Get information about a data type. Depending on the whatInfo flag this routine will return information about the data type through the info parameter. A pointer must be passed to this routine which must point to a variable of the proper type to contain the information which will be returned. This pointer is passed as a void pointer through the info parameter. Below is a table of the flags that determine what information is returned, the type of the variable that is used to store the information in and a description of the information that is returned.

| dipf_DataTypeGetInfo | type | description |
|----------------------|------------------------|-----------------------------|
| DIP_DT_INFO_PROPS | dip_DataTypeProperties | a set of flags as shown in |
| | | the table below |
| DIP_DT_INFO_SIZEOF | dip_int | sizeof(data type) |
| DIP_DT_INFO_C2R | dip_DataType | for complex types returns |
| | | the corresponding floating |
| | | point type (i.e. |
| | | dip_scomplex -> |
| | | dip_sfloat) for other data |
| | | types returns the data type |
| | | itself |

The following table shows which dip_DataTypeProperties flags are set for which data types:

| Data type identifier group | data types |
|----------------------------|--|
| DIP_DT_IS_UINT | unsigned integer |
| DIP_DT_IS_UNSIGNED | unsigned integer |
| DIP_DT_IS_SINT | signed integer |
| DIP_DT_IS_INT | signed and unsigned integer |
| DIP_DT_IS_INTEGER | signed and unsigned intege |
| DIP_DT_IS_FLOAT | floating-point |
| DIP_DT_IS_REAL | integer and floating-point |
| DIP_DT_IS_COMPLEX | complex floating-point |
| DIP_DT_IS_SIGNED | signed integer, floating-point and complex |
| DIP_DT_IS_BINARY | binary |
| DIP_DT_IS_ANY | all |

Derivative

Derivative filter

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_Derivative ( in, out, boundary, ps, sigmas, order, truncation,
flavour )
```

DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float**

FUNCTION

This function provides a common interface to different families of regularised derivative operators. Which family is used, is specified by the flavour parameter. The order of the derivative operator along each of the cartesian axes may be specified independently.

Be sure to read the documentation on the underlying implementation to learn about the properties and limitations of the various families.

For the Gaussian family of filters, sigmas must be given, but order can be 0 (only smooth, don't take the derivative).

For the finite difference filter, sigmas can be 0, in which case the non-derivative dimensions will not be processed. Any element of sigmas that is non-zero where the corresponding order is zero, indicates a dimension that will be smoothed. Note it's possible to reporduce the SobelGradient filter this way.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|------------|-----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | bc | Boundary conditions |
| dip_BooleanArray | ps (0) | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_int | order (0) | Derivative order |
| dip_float | truncation | Truncation, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative filter flavour |

The enumerator flavour parameter is one of:

| Name | Description |
|-------------------|--|
| DIP_DF_DEFAULT | Default derivative flavour (==DIP_DF_FIRGAUSS) |
| DIP_DF_FIRGAUSS | Gaussian family, FIR implementation, Gauss |
| DIP_DF_IIRGAUSS | Gaussian family, IIR implementation, GaussIIR |
| DIP_DF_FTGAUSS | Gaussian family, FT implementation, GaussFT |
| DIP_DF_FINITEDIFF | Finite difference implementation, FiniteDifferenceEx |

SEE ALSO

See section 9.5, "Derivative-based operations", in Fundamentals of Image Processing.

Dgg

Second order derivative filter

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_Dgg ( in, out, boundary, ps, sigmas, tc, flavour )
```

DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float**

FUNCTION

Computes the second derivative in gradient direction of an image using the Derivative function.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|----------|-----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | ps | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_float | tc | Truncation of Gaussian, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative flavour |

The enumerator flavour parameter is one of:

| Name | Description |
|-------------------|--|
| DIP_DF_DEFAULT | Default derivative flavour (==DIP_DF_FIRGAUSS) |
| DIP_DF_FIRGAUSS | Gaussian family, FIR implementation, Gauss |
| DIP_DF_IIRGAUSS | Gaussian family, IIR implementation, GaussIIR |
| DIP_DF_FTGAUSS | Gaussian family, FT implementation, GaussFT |
| DIP_DF_FINITEDIFF | Finite difference implementation, FiniteDifferenceEx |

 ${\tt Derivative, GradientMagnitude, GradientDirection2D, Laplace, LaplacePlusDgg, LaplaceMinDgg}$

Dilation

Local maximum filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Dilation ( in, out, se, boundary, param, shape )
```

DATA TYPES

integer, float, binary

FUNCTION

Grey-value dilation with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

${\tt dip_PixelGetFloat}$

Midlevel PixelIO function

SYNOPSIS

dip_Error dip_PixelGetFloat (vptr, type, position, stride, plane, val)

FUNCTION

The dip_PixelGet/SetInteger and dip_PixelGet/SetFloat functions provide midlevel access to image pixel values. These functions are faster than the highlevel Get and Set functions, but are easier to use than the lowlevel DIP_PIXEL_GET and DIP_PIXEL_SET macros as defined in dip_macros.h.

ARGUMENTS

| Data type | Name | Description |
|------------------|----------|--|
| void * | vptr | Void pointer to the image data |
| dip_DataType | type | Image data type. See DIPlib's data types |
| dip_IntegerArray | position | Position of the pixel in the image |
| dip_IntegerArray | stride | Image data stride |
| dip_int | plane | Plane of the pixel (binary images) |
| dip_float * | val | Pointer to the variable receiving the obtained pixel |
| | | value |

DirectedPathOpening

Morphological filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error DirectedPathOpening ( grey, mask, out, param, closing, constrained
)
```

DATA TYPES

binary, integer, float

FUNCTION

Theoretically, the path opening can be written as the supremum of all the openings with each of the possible linear structuring elements of composed of a set number of pixels in the general orientation of param. The param parameter is interpreted as follows: length is set to max(param). direction is set to round(param/length). direction now contains only values 0, -1 or 1. A 90 degree cone is defined around the given direction, and this cone gives the neighbourhood connectivity. The structuring element is formed by length pixels connected according to this neighbourhood connectivity. For example, in 2D, if param is [10,0], the structuring element will be formed by 10 pixels connected either diagonally or horizontally. It will extend across exactly 10 horizontal pixels, but can vary in shape to adapt to local image content.

If closing is DIP_TRUE, the path closing will be computed instead of the opening.

If constrained is DIP_TRUE, the algorithm is modified as follows: Only one consecutive step is allowed in a direction other than the exact direction specified. For example, following the [10,0] example above, a diagonal step must be followed by at least one horizontal step. This avoids zig-zag lines, especially if the main direction is diagonal. It also reduces the maximal angle that a straight line can deviate from the chosen direction. The unconstrained algorithm will keep lines rotated by up to 45 degrees; the constrained algorithm limits this to 22.5 degrees.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|---|
| dip_Image | grey | Grey-value input image |
| dip_Image | mask | Mask image for ROI processing |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_FloatArray | param | Size of structuring element |
| dip_Boolean | closing | DIP_FALSE for path opening, DIP_TRUE for path closing |
| dip_Boolean | constrained | DIP_TRUE for constrained paths, DIP_FALSE for the |
| | | original path opening algorithm |

Div

arithmetic function

SYNOPSIS

dip_Error dip_Div (in1, in2, out)

DATA TYPES

binary, integer, float, complex

FUNCTION

This function computes out = in1 / in2 on a pixel by pixel basis. If a pixel in in2 has the value of zero, the corresponding pixel in out will be set to zero. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description |
|---|------|--------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input |
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in2 | Second input |

EdgeObjectsRemove

Remove binary edge objects

SYNOPSIS

```
#include "dip_binary.h"
dip_Error dip_EdgeObjectsRemove ( in, out, connectivity )
```

DATA TYPES

binary

FUNCTION

The function EdgeObjectsRemove removes those binary objects from in which are connected to the edges of the image. The connectivity of the objects is determined by connectivity. This function is a front-end to BinaryPropagation. It calls BinaryPropagation with no seed image and the edge pixels turned on. The result of the propagation is xor-ed with the input image. The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP_TRUE) or as background (DIP_FALSE).

See section 10.3, "Segmentation", in Fundamentals of Image Processing for a description of the edge object removal operation.

ARGUMENTS

| Data type | Name | Description |
|---|--------------|--------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in | Binary input image |
| dip_Image | out | Output |
| dip_int | connectivity | Pixel connectivity |

KNOWN BUGS

This function is only implemented for images with a dimension up to three.

SEE ALSO

BinaryPropagation, Xor

EllipticDistanceToPoint

Distance generation function

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_EllipticDistanceToPoint ( output, origin, scale )
```

DATA TYPES

Output: sfloat

FUNCTION

Computes the elliptic distance of each pixel in the output image to a point at origin. The coordinates of origin may lie outside the image. The scale parameter may be used to specify the relative distance between pixels in each dimension.

ARGUMENTS

| Data type | Name | Description | |
|---|--------|--|--|

Equal

Compare grey values in two images

SYNOPSIS

dip_Error dip_Equal (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function sets each pixel in out to "true" when corresponding pixels in in1 and in2 are equal. This is the same as Compare with the DIP_SELECT_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to SelectValue.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| ${\tt dip_Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| dip_Image | out | Output |

SEE ALSO

Compare, Threshold, Greater, Lesser, NotEqual, NotGreater, NotLesser, SelectValue, NotZero

Erf

mathematical function

SYNOPSIS

dip_Error dip_Erf (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the error function of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------|------|-------------|
| $dip_{-}Image$ | in | Input |
| dip_Image | out | Output |

SEE ALSO

BesselJO, BesselJI, BesselJN, BesselYO, BesselYI, BesselYN, LnGamma, Erfc, Sinc

DIPlib function reference

165

Erfc

mathematical function

SYNOPSIS

dip_Error dip_Erfc (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the complementary error function of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| ${\tt dip_Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

BesselJO, BesselJO, BesselJN, BesselYO, BesselYO, BesselYN, LnGamma, Erf, Sinc

ErfClip

Point Operation

SYNOPSIS

```
#include "dip_point.h"
dip_Error dip_ErfClip ( in, out, threshold, range, clipFlag )
```

DATA TYPES

integer, float

FUNCTION

Clips in using the erf function at either or both the values threshold +/- range/2. If the flag DIP_CLIP_LOW_AND_HIGH_BOUNDS is specified, threshold and range are used as lower and upper bounds respectively.

ARGUMENTS

| Data type | Name | Description | |
|-----------|-----------|-----------------|--|
| dip_Image | in | Input image | |
| dip_Image | out | Output image | |
| dip_float | threshold | Threshold value | |
| dip_float | range | Range value | |
| dipf_Clip | clipFlag | clipFlag | |

The following dipf_Clip flags are defined:

| Name | Description |
|------------------------------|---|
| DIP_CLIP_BOTH | clip both the lower and upper bound |
| DIP_CLIP_LOW | clip lower bound only |
| DIP_CLIP_HIGH | clip upper bound only |
| DIP_CLIP_THRESHOLD_AND_RANGE | same as DIP_CLIP_BOTH |
| DIP_CLIP_LOW_AND_HIGH_BOUNDS | use threshold and range as lower and upper bounds |

SEE ALSO

Clip, ContrastStretch

Erosion

Local minimum filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Erosion ( in, out, se, boundary, param, shape )
```

DATA TYPES

integer, float, binary

FUNCTION

Grey-value erosion with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

error.h

Contains error messages

SYNOPSIS

#include "dip_error.h"

FUNCTION

Contains a lot of definitions to do with DIPlib's error mechanism. In particular, this include file contains definitions for a number of error messages. These are all of the type extern const char *. A list of the error sorted by category follows below:

Memory allocation

| Name | Description |
|---------------------------------|------------------------------|
| dip_errorCouldNotAllocateMemory | No memory could be allocated |

Image creation errors

| Name | Description |
|--|---|
| $	ext{dip_errorImageIsLocked}$ | Image is locked |
| $	ext{dip_errorImageNotRaw}$ | Image is not in the RAW state |
| $	exttt{dip_errorImageNotValid}$ | Image is not in the VALID state |
| $	ext{dip_errorImagesNotUnique}$ | Image is used as an output image more than once |
| $\mathtt{dip_errorImageLockInvalidKey}$ | Cannot unlock. Wrong key |

Image type errors

| Name | Description |
|---|---|
| $	ext{dip_errorIllegalImageType}$ | Illegal image type |
| $\verb"dip_errorImageTypeDoesNotExist"$ | Image type does not exist |
| $	ext{dip_errorImageTypeAlreadyExists}$ | Adding image type failed. Type already exists |
| $	ext{dip_errorImageTypeNotSupported}$ | Image type not supported |
| $\verb"dip_errorImageTypeHandlerMissing"$ | No type handler for image type |

Image data type errors

| Name | Description |
|---------------------------------------|-------------------------|
| ${	t dip_errorDataTypeNotSupported}$ | Data type not supported |
| dip_errorIllegalDataType | Illegal data type |

Image dimension(ality) errors

| Name | Description |
|---|------------------------------|
| $	ext{dip_errorIllegalDimensionality}$ | Illegal dimensionality |
| dip_errorDimensionalityNotSupported | Dimensionality not supported |
| dip_errorIllegalDimension | Illegal dimension |

ErrorFree

Free a DIPlib call tree

SYNOPSIS

void dip_ErrorFree(error)

FUNCTION

Free a DIPlib call tree.

ARGUMENTS

| Data type | Name | Description |
|-----------|-------|------------------|
| dip_Error | error | DIPlib call tree |

RETURNS

Nothing

EuclideanDistanceToPoint

Distance generation function

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_EuclideanDistanceToPoint ( output, origin )
```

DATA TYPES

Output: sfloat

FUNCTION

Computes the Euclidean distance of each pixel in the output image to a point at origin. The coordinates of origin may lie outside the image.

ARGUMENTS

| Data type | Name | Description |
|---|--------|---------------------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | output | Output Image |
| dip_FloatArray | origin | Coordinates of the Origin |

SEE ALSO

EllipticDistanceToPoint, CityBlockDistanceToPoint

EuclideanDistanceTransform

Euclidean distance transform

SYNOPSIS

```
#include "dip_distance.h"
dip_Error dip_EuclideanDistanceTransform ( in, out, distance, border, method
)
```

DATA TYPES

binary

FUNCTION

This function computes the Euclidean distance transform of an input binary image using the vector-based method as opposed to the chamfer method. This method computes distances from the objects (binary 1's) to the nearest background (binary 0's) of in and stored the result in out. The out image is a sfloat type image.

The distance parameter can be used to specify anisotropic sampling densities. If it is set to zero, the sampling density is assumed to be 1.0 along all axes.

The border parameter specifies whether the edge of the image should be treated as objects (border = DIP_TRUE) or as background (border = DIP_FALSE).

Individual vector components of the Euclidean distance transform can be obtained with the VectorDistanceTransform.

ARGUMENTS

| Data type | Name | Description |
|------------------------|----------|--------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_FloatArray | distance | Sampling distances |
| dip_Boolean | border | Image border type |
| dipf_DistanceTransform | method | Transform method |

dipf_DistanceTransform defines the following distance transform types:

| Name | Description |
|---------------------|---|
| DIP_EDT_FAST | fastest, but most errors |
| DIP_EDT_TIES | slower, but fewer errors |
| DIP_EDT_TRUE | slow, uses lots of memory, but is "error free" |
| DIP_EDT_BRUTE_FORCE | gives a result from which errors are calculated for the other |
| | methods. This method is extremly slow and should only be used |
| | for testing purposes. |

LITERATURE

Danielsson, P.E. (1980). "Euclidean distance mapping." Computer Graphics and Image Processing 14: 227-248.

Mullikin, J.C. (1992). "The vector distance transform in two and three dimensions." CVGIP: Graphical Models and Image Processing 54(6): 526-535.

Ragnemalm, I. (1990). Generation of Euclidean Distance Maps, Thesis No. 206. Licentiate thesis. Linkoing University, Sweden.

Ye, Q.Z. (1988). "The signed Euclidean distance transform and its applications." in Proceedings, 9th International Conference on Pattern Recognition, Rome, 495-499.

KNOWN BUGS

The EDT_TRUE transform type is prone to produce an internal buffer overflow when applied to larger (almost) spherical objects. It this cases use EDT_TIES or EDT_BRUTE_FORCE instead.

The option border = DIP_FALSE is not supported for EDT_BRUTE_FORCE.

This function supports 2 and 3-dimensional images.

EuclideanSkeleton

binary skeleton operation

175

SYNOPSIS

#include "dip_binary.h"
dip_Error dip_EuclideanSkeleton (in, out, endpixelCondition, edgeCondition)

DATA TYPES

binary

FUNCTION

This function calculates an accurate (euclidean)skeleton. It tests Hilditch conditions to preserve topology. The algorithms uses the following distance metrics:

2D

12

| 5 | 4-connected neighbor |
|-----------------|--|
| 7 | 8-connected neighbor |
| 11 | neighbors reachable with a knight's move |
| $\overline{3D}$ | |

| 4 | 6-connected neighbors |
|----|--|
| 6 | 18-connected neighbors |
| 7 | 26-connected neighbors |
| 9 | neighbors reachable with knight's move |
| 10 | (2,1,1) neighbors |

The edge parameter specifies whether the border of the image should be treated as object (DIP_TRUE) or as background (DIP_FALSE). See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of the skeleton operation.

(2,2,1) neighbors

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-------------------|--------------------|
| dip_Image | in | Binary input image |
| dip_Image | out | Output image |
| dip_EndpixelCondition | endpixelCondition | Endpixel condition |
| dip_Boolean | edgeCondition | Edge condition |

The dip_EndpixelCondition enumeration consists of the following flags:

| Name | Description |
|--|---------------------------------|
| DIP_ENDPIXEL_CONDITION_LOOSE_ENDS_AWAY | Loose ends are eaten away |
| DIP_ENDPIXEL_CONDITION_NATURAL | "natural" endpixel condition of |
| | this algorithm |
| DIP_ENDPIXEL_CONDITION_KEEP_WITH_ONE_NEIGHBOR | Keep endpoint if it has a |
| | neighbor |
| DIP_ENDPIXEL_CONDITION_KEEP_WITH_TWO_NEIGHBORS | Keep endpoint if it has two |
| | neighbors |
| DIP_ENDPIXEL_CONDITION_KEEP_WITH_THREE_NEIGHBORS | Keep endpoint if it has three |
| | neighbors |

KNOWN BUGS

EuclideanSkeleton is only implemented for 2 and 3 D images.

EuclideanSkeleton does not process pixels in a 2-pixel border around the edge. If this is an issue, consider adding 2 pixels on each side of your image.

The function is buggy for 3D images. DIP_ENDPIXEL_CONDITION_LOOSE_ENDS_AWAY and DIP_ENDPIXEL_CONDITION_KEEP_WITH_ONE_NEIGHBOR produce the same result as DIP_ENDPIXEL_CONDITION_KEEP_WITH_THREE_NEIGHBORS. Both

DIP_ENDPIXEL_CONDITION_NATURAL and

DIP_ENDPIXEL_CONDITION_KEEP_WITH_TWO_NEIGHBORS produce resonable results under most circumstances, but don't count on it!

ExponentialFitCorrection

Exponential fit based attenuation correction

SYNOPSIS

```
#include "dip_microscopy.h"
dip_Error dip_ExponentialFitCorrection ( in, out, method, percentile,
fromWhere, hysteresis, varWeighted )
```

DATA TYPES

binary, integer, float

FUNCTION

This routine implements a simple absorption, reflection and bleaching correction based upon the assumption that the sum of these effects result in a exponential extinction of the signal as a function of depth. Only pixels that are non-zero are taken into account. Depending upon the chosen method, the mean or a percentile of all the non-zero pixels are calculated as a function of the slice number (depth). Then an exponential function is fitted through these slice-representing values. The starting point of the fit is determined by from Where. The first maximum is found with point [z+1] > b hysteresis * point [z]. If the mean variant is chosen one can chose to apply a variance weighting to the fit.

ARGUMENTS

| Data type | Name | Description |
|------------------|-------------|-----------------------------|
| $dip_{-}Image$ | in | Input image |
| dip_Image | out | Output image |
| dipf_ExpFitData | method | Data statistic to fit on |
| dip_float | percentile | Percentile |
| dipf_ExpFitStart | fromWhere | From where to start the fit |
| dip_float | hysteresis | First maximum hysteresis |
| dip_Boolean | varWeighted | Fit with variance weights |

The dipf_ExpFitData enumaration consists of the following flags:

| Name | Description |
|---|---|
| DIP_ATTENUATION_EXP_FIT_DATA_MEAN | Fit on the mean values |
| DIP_ATTENUATION_EXP_FIT_DATA_PERCENTILE | Fit on the specified percentile of the data |

The dipf_ExpFitStart enumaration consists of the following flags:

| Name | Description |
|--|-----------------------------|
| DIP_ATTENUATION_EXP_FIT_START_FIRST_PIXEL | Start fit on first pixel |
| DIP_ATTENUATION_EXP_FIT_START_GLOBAL_MAXIMUM | Start fit on global maximum |
| DIP_ATTENUATION_EXP_FIT_START_FIRST_MAXIMUM | Start fit on first maximum |

ExtendRegion

Image manipulation functions

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_ExtendRegion ( image, origin, regDims, bc, ordering, imValues )
```

FUNCTION

This functions extends a region in an image, defined by origin and regDims, with a specified boundary condition bc. The pixels outside the region are modified according to bc. ordering changes the order in which the dimensions are processed, set to 0 to use default process order.

ARGUMENTS

| Data type | Name | Description |
|--|----------|-------------------------|
| dip_Image | image | Image, will be modified |
| $\mathtt{dip}_{\mathtt{-}}\mathtt{IntegerArray}$ | origin | Origin of region |
| dip_IntegerArray | regDims | Size of region |
| dip_BoundaryArray | bc | Boundary conditions |
| dip_IntegerArray | ordering | Ordering of dimensions |
| dip_Image * | imValues | Unused, set to 0. |

NOTE

Boundary conditions DIP_BC_ZERO_ORDER_EXTRAPOLATE, DIP_BC_FIRST_ORDER_EXTRAPOLATE and DIP_BC_SECOND_ORDER_EXTRAPOLATE are not supported.

FeatureAnisotropy2D

Measure the anisotropy in a labeled region

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureAnisotropy2DID ( void )
```

OUTPUT DATA TYPE

dip_float

FUNCTION

dip_FeatureAnisotropy2DID returns the ID value of this measurement function, that is registered by Initialise.

The grey value input image should contain an orientation field. For each labeled region, a tensor is constructed at each of the region's pixels. This tensor is as follow:

```
cos^2(phi) cos(phi)sin(phi)
[
cos(phi)sin(phi) sin^2(phi)
```

The next step is to compute a new tensor, each element computed by averaging the corresponding elements of all the individual tensors. This average tensor represents the orientation information of the region as a whole. Eigenvalue analysis of this tensor yields two eigenvalues, the largest 10, the smallest 11. The anisotropy measure is:

```
(10 - 11) / (10 + 11)
```

which is zero for a fully isotropic regions (i.e. one where there is no preferred orientation), and one for a fully anisotropic region (i.e. when there is a single orientation).

NOTE

This function ignores any physical dimensions passed through the Measure function.

SEE ALSO

Measure

FeatureBendingEnergy

Undocumented measurement function

FUNCTION

This measurement function is undocumented and not meant for public use. Measure

FeatureCenter

Measure the object's center

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureCenterID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureCenterID returns the ID value of this measurement function, that is registered by Initialise.

This functions measures the centre of an object by calculating the first moments of the object using the object labels as binary mask. The intensity information is not taken into account.

SEE ALSO

Measure

FeatureChainCodeBendingEnergy

Undocumented measurement function

FUNCTION

This measurement function is undocumented and not meant for public use.

NOTE: this function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

Measure

FeatureChainCodeFunction

Measurement feature #measure function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureChainCodeFunction) ( measurement, featureID, objectID, chaincode, iterations )
```

FUNCTION

The chaincode measure function is meant for 2-D measurement functions that only require information on the shape of the object's contour, such as FeaturePerimeter. The chaincode function is called for each object seperately, with the contour of that object stored in chaincode.

ARGUMENTS

| Data type | Name | Description | |
|-----------------|-------------|--|--|
| dip_Measurement | measurement | Measurement data structure | |
| dip_int | featureID | Measurement function ID | |
| dip_int | objectID | ID of the object to be measured | |
| dip_ChainCode | chaincode | Chaincode data structure encoding the object's | |
| | | contour | |
| dip_int | iterations | Number of iterations the measure function needs to | |
| | | scan the data | |

${\tt Feature Compose Function}$

Measurement feature #compose function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureComposeFunction) ( measurement, featureID, label,
intensity, compositeFeatureID, resources )
```

FUNCTION

The compose function is called to obtain a list of measurement features. These features are measured before the measure function of a composite feature is called (FeatureCompositeFunction). This parameter is ignored for other measurement types. The compose function is called after the create function (FeatureCreateFunction).

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------------|--|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement feature function ID |
| $\mathtt{dip}_{-}\mathtt{Image}$ | label | Image with pixel intensities represending |
| | | object IDs |
| dip_Image | intensity | Image containing corresponding intensity |
| | | values |
| dip_IntegerArray * | compositeFeatureID | Pointer to an integer array containing the |
| | | the IDs of the measurement features this |
| | | function requires |

FeatureCompositeFunction

Measurement feature #measure function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureCompositeFunction) ( measurement, featureID, objectID,
composite, iterations )
```

FUNCTION

The composite measure function is meant for measurement function that derive their measurements from the results of other measurement functions. The measurement functions this function is based on is obtained by calling the compose function (FeatureComposeFunction). The composite measure function obtains the results of these measurements through its composite function parameter. Use the regular measurement structure access method to read the values in this parameter (i.e. MeasurementObjectValue).

ARGUMENTS

| Data type | Name | Description | |
|--------------------------------|-------------|--|--|
| dip_Measurement | measurement | Measurement data structure | |
| $\mathtt{dip}_{-}\mathtt{int}$ | featureID | Measurement function ID | |
| dip_int | objectID | ID of the object to be measured | |
| dip_Measurement | composite | Measurement structure containing the measurement | |
| | | data this function is based on | |
| dip_int | iterations | Number of iterations the measure function needs to | |
| | | scan the data | |

SEE ALSO

FeatureConvertFunction

Measurement feature #convert function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureConvertFunction) ( in, featureID, inID, out, outID,
resources )
```

FUNCTION

The convert function should convert the measurement data of the feature feaureID for the object inID in the measurement in to object outID of measurement out. This function is called by MeasurementFeatureConvert.

ARGUMENTS

| Data type | Name | Description | |
|-----------------|-----------|--|--|
| dip_Measurement | in | Input measurement data structure | |
| dip_int | featureID | Measurement function ID | |
| dip_int | inID | ID of the object in in | |
| dip_Measurement | out | Output measurement data structure | |
| dip_int | outID | ID of the object in out | |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew | |

SEE ALSO

FeatureCreateFunction

Measurement feature #create function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureCreateFunction) ( measurement, featureID, label,
intensity, physDims, params, data, resources )
```

FUNCTION

The create function is called to initialise the measurement function. It should allocate and initialise a memory block for internal use, assign this block to the pointer *data, and register it in resources.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|---|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement feature function ID |
| dip_Image | label | Image with pixel intensities represending |
| | | object IDs |
| dip_Image | intensity | Image containing corresponding intensity |
| | | values |
| dip_PhysicalDimensions | physDims | Physical dimensions data structure |
| void * | params | For future expansion, is currently always |
| | | NULL |
| void ** | data | Pointer to a data block that can later be |
| | | accessed using MeasurementObjectData |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

FeatureDescriptionFree

Free a Feature Description

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionFree ( description )
```

FUNCTION

This function frees a Feature Description data structure. This is not the preferred way of freeing a Feature Description. Use the resources mechanism instead (Resources tracking structure. See ResourcesNew).

ARGUMENTS

| Data type | Name | Description |
|--------------------------|-------------|---------------------------------|
| dip_FeatureDescription * | description | Feature Description to be freed |

SEE ALSO

FeatureDescriptionFunction

Measurement feature #description function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureDescriptionFunction) ( measurement, featureID,
physDims, decription, resources )
```

FUNCTION

The description function should return a dip_FeatureDescription structure containing information on the measurement function, such as its name, a short description, labels for each value measured, and units of its measurement. This function is called by MeasurementFeatureDescription.

The description structure should be allocated by this function using FeatureDescriptionNew, and registered in resources. The functions FeatureDescriptionSetName, FeatureDescriptionSetDescription, FeatureDescriptionSetDimensionLabels and FeatureDescriptionSetUnits should be used to populate the structure.

ARGUMENTS

| Data type | Name | Description |
|--------------------------|-------------|------------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| dip_PhysicalDimensions | physDims | Physical dimensions data structure |
| dip_FeatureDescription * | description | Pointer to a structure containing |
| | | descriptive information of the |
| | | measurement feature function |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

Get the labels of the described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionGetLabels ( description, labels, resources )
```

FUNCTION

Gets the labels of the data of the feature descripted by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| dip_StringArray * | labels | Feature Labels |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

SEE ALSO

${\tt Feature Description GetName}$

Get the name of the described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionGetName ( description, name, resources )
```

FUNCTION

Gets the name of the feature described by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| dip_String * | name | Name of the measurement feature |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

SEE ALSO

${\tt Feature Description Get Units}$

Get the Units of the described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionGetUnits ( description, units, resources )
```

FUNCTION

Gets the units of the data of the feature descripted by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| dip_StringArray * | units | Array of Unit texts |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

SEE ALSO

FeatureDescriptionNew

Allocate a new FeatureDescription

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionNew ( description, resources )
```

FUNCTION

This function allocates a new dip_FeatureDescription data structure. A feature description contains the name, a short description of a measurement feature, as well as the labels and units of the data measured by the feature.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

SEE ALSO

FeatureDescriptionSetDescription

Set the description of the described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionSetDescription ( description, text )
```

FUNCTION

Sets the description of the feature descripted by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| char * | text | Description text |

SEE ALSO

$Feature {\tt DescriptionSetDimensionLabels}$

Label set convenience function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionSetDimensionLabels ( description,
measurement, featureID, baseLabel )
```

FUNCTION

This function set the labels of the feature, described by description, by adding for each label a dimension indicator to baseLabel. For dimensions 0 to 3, X, Y or Z is added. For dimensions higher, the numerical value of the dimension is added.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | ID of the measurement feature |
| char * | baseLabel | Base label |

SEE ALSO

${\tt Feature Description Set Label}$

Set the name of a particular feature label

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionSetLabel ( description, number, label )
```

FUNCTION

This function sets the name of a particular label of the described feature.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| dip_int | number | Index of the label |
| char * | label | Label text |

SEE ALSO

FeatureDescriptionSetLabels

Set the labels of the described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionSetLabels ( description, measurement, featureID, labels, label )
```

FUNCTION

Sets the labels of the data of the feature descripted by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|--|
| dip_FeatureDescription | description | Feature description data structure |
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | ID of the measurement feature |
| dip_StringArray | labels | Array of label describing strings, one for |
| | | each label |
| char * | label | Single description of all feature labels |

SEE ALSO

FeatureDescriptionSetName

Set the name of the described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionSetName ( description, name )
```

FUNCTION

Sets the name of the feature descripted by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|------------------------------------|
| dip_FeatureDescription | description | Feature description data structure |
| char * | name | Name of the measurement feature |

SEE ALSO

FeatureDescriptionSetUnits

Set the units of a described feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionSetUnits ( description, measurement, featureID, units, unit )
```

FUNCTION

Sets the units of the data of the feature descripted by description.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|--|
| dip_FeatureDescription | description | Feature description data structure |
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | ID of the measurement feature |
| dip_StringArray | units | Array of Unit texts, one for each unit |
| char * | unit | Single text for all units |

SEE ALSO

FeatureDimension

207

Measure the object's dimensions

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureDimensionID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureDimensionID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the length of an object along the principal axes of the label image (e.g. the length object along the X, Y & Z axes).

SEE ALSO

Measure

FeatureExcessKurtosis

Undocumented measurement function

FUNCTION

This measurement function is undocumented and not meant for public use. Measure

FeatureFeret

209

Measure the object's Feret diameters

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureFeretID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureFeretID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the Feret maximum and minimum diameters of an object. The Feret diameter are found by rotating the object's chain code. The default angle step size is defined by DIP_MSR_FERET_ACCURACY (set to 0.5 degrees). This measurement function supports a measurement parameter (see Measure), which is defined in dip_measurement.h. If a non-zero pointer to a dip_FeretParameters structure is supplied, the structure's stepsize parameter is used instead of the default angle step size. Furthermore the structure's angles Boolean parameter specifies whether the angles of the Feret diameters should be measured as well. This function supports 2D images only.

ARGUMENTS

| Data type | Name | Description |
|---------------------|--------|---|
| dip_FeretParameters | *feret | Pointer to a Feret measurement parameters structure |
| | | (not yet implemented) |

NOTE

If any physical dimensions are passed to this function through Measure, only the sample distance along the first dimension are used. All other dimensions are assumed to be sampled the same way. This produces incorrect results for anisotropically sampled images.

NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

CREDITS

The original code on which the current implementation is based, was donated by Gerie van der Heijden.

FeatureGinertia

Measure the object's inertia

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureGinertiaID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureGinertiaID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia (weighted by its grey values) of an object by calculating the eigenvalues of the object's second order moments tensor. This measure only supports 2D and 3D objects. FeatureGinteria supports a measurement parameter (see Measure). If a pointer to a non-zero Boolean is supplied, this function will not only measure the eigenvalues of the second order moments tensor, but also the angles of its eigenvectors.

ARGUMENTS

| Data type | Name | Description |
|---------------|--------|--|
| dip_Boolean * | angles | Pointer to a Boolean specifying that "eigenangles" should be |
| | | measured (not yet implemented) |

NOTE

If any physical dimensions are passed to this function through Measure, only the sample distance along the first dimension are used. All other dimensions are assumed to be sampled the same way. This produces incorrect results for anisotropically sampled images.

FeatureGmu

Measure the object's inertia

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureGmuID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureGmuID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia (weighted by its grey values) of an object by calculating the object's second order moments tensor. This measure only supports 2D and 3D objects. The output tensor is ordered as follows:

```
2D: xx, xy, yy
3D: xx, xy, xz, yy, yz, zz
```

NOTE

If any physical dimensions are passed to this function through Measure, only the sample distance along the first dimension are used. All other dimensions are assumed to be sampled the same way. This produces incorrect results for anisotropically sampled images.

FeatureGravity

Measure the object's gravity

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureGravityID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureGravityID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the point of gravity of the object, by calculating the object's first moment weighted by the intensity of each object pixel.

SEE ALSO

Measure

FeatureImageFunction

Measurement feature #measure function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureImageFunction) ( measurement, featureID, label,
intensity, objectID, iterations )
```

FUNCTION

The image measurement function is meant for measurement operation that need neighborhood or global object shape information for its operation (e.g. the FeatureSurfaceArea function needs to evaluate the 6 connected neighborhood of each boundary voxel). The object ID image label can contain values that are not present in objectID. These labels should be ignored.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|--|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| $\mathtt{dip}_{-}\mathtt{Image}$ | label | Image with pixel intensities represending object IDs |
| $\mathtt{dip}_{-}\mathtt{Image}$ | intensity | Image containing corresponding intensity values |
| dip_IntegerArray | objectID | Array of objectIDs to be measured |
| dip_int | iterations | Number of iterations the measure function needs to |
| | | scan the image |

FeatureInertia

217

Measure the object's inertia

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureInertiaID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureInertiaID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia of an object by calculating the eigenvalues of the object's second order moments tensor. This measure only supports 2D and 3D objects. FeatureInteria supports a measurement parameter (see Measure). If a pointer to a non-zero Boolean is supplied, this function will not only measure the eigenvalues of the second order moments tensor, but also the angles of its eigenvectors.

ARGUMENTS

| Data type | Name | Description |
|---------------|--------|--|
| dip_Boolean * | angles | Pointer to a Boolean specifying that "eigenangles" should be |
| | | measured (not yet implemented) |

NOTE

If any physical dimensions are passed to this function through Measure, only the sample distance along the first dimension are used. All other dimensions are assumed to be sampled the same way. This produces incorrect results for anisotropically sampled images.

Measure

FeatureLineFunction

Measurement feature #measure function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureLineFunction) ( measurement, featureID,
label,intensity, size, objectID, dim, iterations )
```

FUNCTION

The line measure function obtains two arrays (label and intensity) with label and intensity information of the objects to be measured. The line measurement function is called for every line in the image (the scan dimension is determined at run time to be optimal). Since label can contain more than one different label, line itself is responsible for storing the measurement results for the appropriate object (using, for example, MeasurementObjectData). The object ID array label can contain values that are not present in objectID. These labels should be ignored.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|-------------|---|
| dip_Measurement | measurement | Measurement data structure |
| $\mathtt{dip}_{-}\mathtt{int}$ | featureID | Measurement function ID |
| dip_sint32 * | label | Pointer to a list (image line) of object IDs |
| dip_float * | intensity | Pointer to a list of corresponding intensity values |
| dip_int | size | Size of the label and intensity list |
| dip_IntegerArray | objectID | Array of objectIDs to be measured |
| $\mathtt{dip}_{-}\mathtt{int}$ | dim | Dimension of the line, see ScanFrameWork |
| dip_int | iterations | Number of iterations the measure function needs to |
| | | scan the line |

Undocumented measurement function

FUNCTION

This measurement function is undocumented and not meant for public use.

NOTE: this function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

Measure

DIP*lib* function reference

FeatureMass

Measure the mass of the object (sum of grey-values)

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureMassID ( void )
```

OUTPUT DATA TYPE

FUNCTION

dip_FeatureMassID returns the ID value of this measurement function, that is registered by Initialise. This function is just an alias for dip_FeatureSumID.

This function measures the sum of the grey-value in the intensity image (see Measure) of pixels inside the object, and is equivalent to FeatureSum

SEE ALSO

Measure

FeatureMaximum

Measure the object's maximum coordinate value

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureMaximumID ( void )
```

OUTPUT DATA TYPE

dip_IntegerArray, dip_FloatArray

FUNCTION

dip_FeatureMaximumID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the maximum coordinate value of each dimension of the object.

If a dip_PhysicalDimensions parameter is given to Measure, the maximum coordinate of the object is given in physical units, and is a dip_FloatArray rather than a dip_IntegerArray.

SEE ALSO

Measure

DIP*lib* function reference 223

FeatureMaxVal

Measure the object's maximum intensity

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureMaxValID ( void )
```

OUTPUT DATA TYPE

dip_float

FUNCTION

dip_FeatureMaxValID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the maximum intensity in the intensity image (see Measure) of pixels inside the object.

SEE ALSO

Measure

FeatureMean

Measure the object's mean intensity

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureMeanID ( void )
```

OUTPUT DATA TYPE

dip_int dip_FeatureMinimumID ( void )
```

OUTPUT DATA TYPE

dip_IntegerArray, dip_FloatArray

FUNCTION

dip_FeatureMinimumID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the minimum coordinate value of each dimension of the object.

If a dip_PhysicalDimensions parameter is given to Measure, the minimum coordinate of the object is given in physical units, and is a dip_FloatArray rather than a dip_IntegerArray.

SEE ALSO

Measure

FeatureMinVal

Measure the object's minimum intensity

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureMinValID ( void )
```

OUTPUT DATA TYPE

dip_float

FUNCTION

dip_FeatureMinValID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the minimum intensity in the intensity image (see Measure) of pixels inside the object.

SEE ALSO

Measure

DIP*lib* function reference

FeatureMu

Measure the object's inertia

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureMuID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureMuID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia of an object by calculating the object's second order moments tensor. This measure only supports 2D and 3D objects. The output tensor is ordered as follows:

```
2D: xx, xy, yy3D: xx, xy, xz, yy, yz, zz
```

NOTE

If any physical dimensions are passed to this function through Measure, only the sample distance along the first dimension are used. All other dimensions are assumed to be sampled the same way. This produces incorrect results for anisotropically sampled images.

FeatureOrientation2D

Undocumented measurement function

FUNCTION

This measurement function is undocumented and not meant for public use. Measure

FeatureP2A

Measure the circularity of the object

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureP2AID ( void )
```

OUTPUT DATA TYPE

dip_float

FUNCTION

dip_FeatureP2AID returns the ID value of this measurement function, that is registered by Initialise.

This function is a composite measurement function, that uses FeatureSize,
FeaturePerimeter, and FeatureSurfaceArea to determine the circularity of an object by
calculating: 2D: P2A = perimeter^2 / (4Pi * size) 3D: P2A = surface-area^1.5 /
(6 Sqrt(Pi) * size)

NOTE

This function ignores any physical dimensions passed through the Measure function. The units are always pixels.

NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

FeaturePerimeter

Measure the object's perimeter length

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeaturePerimeterID ( void )
```

OUTPUT DATA TYPE

dip_float

FUNCTION

dip_FeaturePerimeterID returns the ID value of this measurement function, that is registered by Initialise.

This measures the perimeter of 2D objects by calculating the length of the chain code of its enclosing border. This function assumes that each object has a single connected border. The used method for measuring the length of the chain code is optimal for circles, and for a collection of objects that are randomly oriented, see the referenced literature for details.

NOTE

If any physical dimensions are passed to this function through Measure, only the sample distance along the first dimension are used. All other dimensions are assumed to be sampled the same way. This produces incorrect results for anisotropically sampled images.

NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

FeatureShape

Measure shape parameters of the object

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureShapeID ( void )
```

OUTPUT DATA TYPE

dip_FloatArray

FUNCTION

dip_FeatureShapeID returns the ID value of this measurement function, that is registered by Initialise.

This function is a composite measurement function, that uses FeatureSize, FeaturePerimeter, and FeatureFeret to measures the following shape characteristics of 2D objects:

```
Squarity = area / ( s * sp )
Circularity = area / ( Pi/4 * sp^2 )
Triangularity = area / ( 2 * s * sp )
Ellipsity = area / ( Pi/4 * s * sp )
Elongation = p / l
```

with area the size, s the shortest Feret diameter, 1 the longest Feret diameter, sp the Feret diameter perpendicular to s, and p the perimeter of the object. The values in the output array are given in this order.

When the measured object is either a perfect square, circle, triangle or ellipse, the values obtained by FeatureShape will be 1.0.

NOTE

This function assumes isotropic sampling, even if the physical dimensions given through the Measure function say otherwise.

NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

SEE ALSO

Measure

FeatureSize

Measure the object's size

SYNOPSIS

```
#include "dip_measurement.h"
dip_int dip_FeatureSizeID ( void )
```

OUTPUT DATA TYPE

dip_int, dip_float

FUNCTION

dip_FeatureSizeID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the object's size by counting the number of pixels having the same object ID. This measure is the optimal procedure for estimating the area (2D) or volume (3D) of an object with an arbitrary size. The measurement value's unit are in pixels (pixels^2 in 2D, pixels^3 in 3D).

If a dip_PhysicalDimensions parameter is given to Measure, the size of the object is given in physical units, and is a dip_float rather than a dip_int.

FillBoundaryArray

245

Fill the border of array according to the boundary condition

SYNOPSIS

dip_Error DIP_TPI_FUNC(dip_FillBoundaryArray)(in, out, size, border, boundary)

FUNCTION

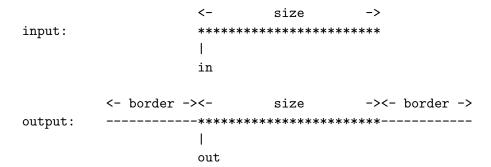

Set the values of the border pixels of an array. The pixels of out outside the range of the array in are set to a value determined by the boundary condition and the pixel values of in.

ARGUMENTS

| Data type | Name | Description | |
|--------------------------------|----------|------------------------------|--|
| void * | in | input array | |
| void * | out | output array | |
| $\mathtt{dip}_{-}\mathtt{int}$ | size | size of input array | |
| dip_int | border | size of the extended borders | |
| dip_Boundary | boundary | Boundary conditions | |

NOTE

The out array has to be allocated before this function is called, and should at least has the size of (size + 2 * border). Thus, border specifies the length of the border on both sides of the in array. Furthermore, the out pointer should point to that element in the out array that corresponds to the first element in the in array:

The enumerator dip_boundary contains the following constants:

| Name | Description |
|----------------------|------------------------------------|
| DIP_BC_SYM_MIRROR | Symmetric mirroring |
| DIP_BC_ASYM_MIRROR | Asymmetric mirroring |
| DIP_BC_PERIODIC | Periodic copying |
| DIP_BC_ASYM_PERIODIC | Asymmetric periodic copying |
| DIP_BC_ADD_ZEROS | Extending the image with zeros |
| DIP_BC_ADD_MAX_VALUE | Extending the image with +infinity |
| DIP_BC_ADD_MIN_VALUE | Extending the image with -infinity |

DIPlib function reference

FindShift

Estimate the shift between images

SYNOPSIS

```
#include "dip_findshift.h"
dip_Error dip_FindShift ( in1, in2, out, method, parameter )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function estimates the (sub-pixel) global shift between in1 and in2. The numbers found represent the shift of in1 with respect to in2, or the position of the first pixel of in2 in the coordinate system of in1. There are two methods that can be used: CPF and MTS. Both methods require that the shift be small. Therefore, first the integer pixel is calculated, and both images are cropped to the common part.

If method is 0, DIP_FSM_MTS is used. method can also be DIP_FSM_INTEGER_ONLY. Integer shifts can be calculated for images of any dimensionality.

CPF

The CPF method (marked as FFTS in the literature below) uses the phase of the cross-correlation (as calculated by CrossCorrelationFT) to estimate the shift. parameter sets the amount of frequencies used in this estimation. The maximum value that makes sense is sqrt(1/2). Any larger value will give the same result. Choose smaller values to ignore the higher frequencies, which have a smaller SNR and are more affected by aliasing. If parameter is set to 0, the optimal found for images sub-sampled by a factor four will be used (parameter = 0.2).

This method only supports 2-D images (until further notice).

MTS

The MTS method (marked as GRS in the literature below) uses a first order Taylor approximation of the equation in1(t) = in2(t-s) at scale parameter. Setting parameter to zero, a scale of 1 will be used. This means that the images will be smoothed with a Gaussian kernel of 1. This is the more accurate one of the two methods, and therefore is the

default.

This method supports images with a dimensionality between 1 and 3.

ITER

The ITER method is an iterative version of the MTS method. It is known that a single gradient based shift estimation have bias due to truncation of the Taylor expansion series (see Pham et.al.) The bias can be expressed as a polynomial of the subpixel displacements. As a result, if Taylor method is applied iteratively and the shift is refined after each iteration, the bias eventually become negligible. By using just 3 iterations, it is possible to correct bias that results in high precision O(1e-6).

PROJ

The PROJ method compute shift in each dimension from images' projections. It is fast and fairly accurate for high SNR. Should not be used for low SNR

ARGUMENTS

| Data type | Name | Description |
|----------------------|-----------|-------------------|
| ${\tt dip_Image}$ | in1 | Input image |
| dip_Image | in2 | Input image |
| dip_FloatArray | out | Estimated shift |
| dipf_FindShiftMethod | method | Estimation method |
| dip_float | parameter | Parameter |

The dipf_FindShiftMethod enumeration consists of the following flags:

| Name | Description |
|----------------------|------------------------------|
| DIP_FSM_DEFAULT | Default method (MTS) |
| DIP_FSM_INTEGER_ONLY | Find only integer shift |
| DIP_FSM_CPF | Use cross-correlation method |
| DIP_FSM_FFTS | Same |
| DIP_FSM_MTS | Use Taylor series method |
| DIP_FSM_GRS | Same |

FiniteDifference

A linear gradient filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_FiniteDifference ( in, out, boundary, processDim, filter )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

The FiniteDifference filter implements several basic one dimensional FIR convolution filters. The dimension in which the operation is to be performed is specified by processDim. The operation itself is selected with filter. The $(1\ 0\ -1)/2$, $(1\ -1\ 0)$ & $(0\ 1\ -1)$ are difference filters that approximate a first order derivative, the $(1\ -2\ 1)$ filter approximates a second order derivative operation. The triangular $(1\ 2\ 1)/4$ filter is a local smoothing filter.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|------------|---------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_int | processDim | ProcessDim |
| dipf_FiniteDifference | filter | Filter selection |

The dipf_FiniteDifference enumeration consists of the following flags:

| Name | Description |
|----------------------------|--|
| DIP_FINITE_DIFFERENCE_M101 | out[ii] = (in[ii+1] - in[ii-1])/2 |
| DIP_FINITE_DIFFERENCE_OM11 | out[ii] = in[ii+1] - in[ii] |
| DIP_FINITE_DIFFERENCE_M110 | $\operatorname{out}[ii] = \operatorname{in}[ii] - \operatorname{in}[ii-1]$ |
| DIP_FINITE_DIFFERENCE_1M21 | out[ii] = in[ii-1] - 2*in[ii] + in[ii+1] |
| DIP_FINITE_DIFFERENCE_121 | out[ii] = (in[ii-1] + 2*in[ii] + in[ii+1])/4 |

FiniteDifferenceEx

A linear gradient filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_FiniteDifferenceEx ( in, out, boundary, process, parOrder,
smoothflag )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

The FiniteDifferenceEx filter implements several basic one dimensional FIR convolution filters. The difference between this function and FiniteDifference is that this one has an interface more similar to Gauss and Derivative: it can process different derivatives along different dimensions at the same time. The first derivative is a convolution with $(1 \ 0 \ -1)/2$, and the second derivative is a convolution with $(1 \ -2 \ 1)$. When parOrder is 0 for a dimension, either the triangular smoothing filter $(1 \ 2 \ 1)/4$ is applied (smoothflag set to DIP_TRUE), or the dimension is not processed at all (smoothflag set to DIP_FALSE).

Setting all process to DIP_TRUE, all parOrder to 0 except one dimension to 1, and smoothflag to DIP_TRUE yields the SobelGradient.

ARGUMENTS

| Data type | Name | Description |
|-------------------|------------|--|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | process | Dimensions to process |
| dip_IntegerArray | parOrder | Order of Derivative along each dimension |
| dip_Boolean | smoothflag | Whether or not to smooth in the non-derivative |
| | | directions |

FloatArrayCopy

Copy an array

SYNOPSIS

dip_Error dip_FloatArrayCopy (dest, src, resources)

FUNCTION

This function copies the float array **src** to **dest**. The array **dest** is created by this function as well.

ARGUMENTS

| Data type | Name | Description |
|------------------|-----------|--|
| dip_FloatArray * | dest | Destination array |
| dip_FloatArray | src | Source array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

BooleanArrayCopy, VoidPointerArrayCopy, StringArrayCopy

FloatArrayFind

Find value in array

SYNOPSIS

dip_Error dip_FloatArrayFind (array, value, index, found)

FUNCTION

Finds a value in an array and "returns" its index in the array. If found is zero, FloatArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP_FALSE if value is not found).

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|--------------------------|
| dip_FloatArray | array | Array to find value in |
| dip_float | value | Value to find |
| dip_int * | index | Index of the found value |
| dip_Boolean * | found | Value found or not |

SEE ALSO

FloatArrayNew

Array allocation function

SYNOPSIS

dip_Error dip_FloatArrayNew (array, size, value, resources)

FUNCTION

This function allocates the size elements of a dip_FloatArray and sets the size of the array to size. Each array element is initialized with value.

ARGUMENTS

| Data type | Name | Description |
|------------------|-----------|--|
| dip_FloatArray * | array | Array |
| dip_int | size | Size |
| dip_float | value | Initial value |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

Floor

Arithmetic function

SYNOPSIS

dip_Error dip_Floor (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the floor of the input image values, and outputs a signed integer typed image.

ARGUMENTS

| Data type | Name | Description |
|----------------|------|-------------|
| $dip_{-}Image$ | in | Input |
| dip_Image | out | Output |

SEE ALSO

Abs, Ceil, Sign, Truncate, Fraction, NearestInt

FourierTransform

Computes the Fourier transform

SYNOPSIS

```
#include "dip_transform.h"
dip_Error dip_FourierTransform ( in, out, trFlags, process, theFuture )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Performs a Fourier transform on in and places the result in out.

Normalisation: 1/sqrt(dimension) for each dimension.

Defaults: process may be zero, indicating that all dimensions should be processed.

Sampling in Fourier Domain (FD): Let one pixel in the spatial domain (SD) be Delta_SD [m], then one pixel in the FD is Delta_FD = $1/(Delta_SD * N)$ [m^-1], where N is the width of the image in pixels. As a consequence the maximal frequency in the FD image is N/2 * $1/(Delta_SD * N) = 1/(2 * Delta_SD)$ [m^-1] and is thus independent of the image width N and only related to the Nyquist frequency. The frequency of one FD pixel is therefore related to the image width N.

Note: In consequence of the above the FD resolution will not be isotropic if the image size are not square.

Note: Spatial zero-padding of the image increases the FD resolution only apparently (empty magnification).

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-------------|---------------------------------------|
| dip_Image | in | Input |
| $dip_{-}Image$ | out | Output |
| dipf_FourierTransform | trFlags | Transform flags |
| dip_BooleanArray | process (0) | Dimensions to process |
| void * | theFuture | For future use, should be set to zero |

The dipf_FourierTransform enumeration consists of the following flags:

| Name | Description |
|----------------|------------------------|
| DIP_TR_FORWARD | Forward transformation |
| DIP_TR_INVERSE | Inverse transformation |

SEE ALSO

FTGaussian

Generates the Fourier transform of a Gaussian

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_FTGaussian ( output, sigma, volume, cutoff )
```

DATA TYPES

Output: sfloat, scomplex

FUNCTION

Generates the Fourier transform of a Gaussian with sigma's sigma. (The Fourier transform of a Gaussian, is a Gaussian.) volume is the integral of the Gaussian in the spatial domain. The cutoff variable can be used to avoid the calculation of the exponent of large negative values, which is can be very time consuming. Values of the exponent that are below cutoff yield a 0 value for the exponent. When cutoff is set to 0 or a positive value, DIP_GENERATION_EXP_CUTOFF is used (it is defined as -50).

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------|---------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | output | Output Image |
| dip_FloatArray | sigma | Sigma of the Gaussian |
| dip_float | volume | Total intensity of the Gaussian |
| dip_float | cutoff | Cutoff value for the exponent |

| dip_IntegerArray | order | order |
| dip_float | truncation | $Truncation, see {\tt GlobalGaussianTruncationGet}$ |

SEE ALSO

GaussIIR

DIP*lib* function reference

Gauss

Gaussian Filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_Gauss ( in, out, boundary, process, sigmas, order, truncation )
```

DATA TYPES

binary, integer, float

FUNCTION

Finite impulse response implementation of a Gaussian convolution filter and Gaussian derivative convolution filters.

The Gaussian kernel is cut off at truncation times the sigma of the filter (in each dimension). The sum of the Gaussian's coefficients is normalised to one. A truncation of zero or less indicates that the global preferred truncation ought to be used, see GlobalGaussianTruncationGet. For the derivatives, the truncation value is increased slightly: the actual value for truncation used is truncation + 0.5*order. The minimum filter size is 3 pixels, or 5 pixels for the 3rd order derivative.

Both the process and the order parameter may be zero. If process is zero all dimensions are processed. If order is zero no derivatives are taken.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-------------|--|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | process (0) | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_IntegerArray | order (0) | Order of Derivative along each dimension |
| dip_float | truncation | Truncation of Gaussian |

LIMITATIONS

The order of the derivative is limited to the interval 0-3. Sigmas considerably smaller than 1.0 will yield nonsensical results.

GaussFT

Gaussian Filter through the Fourier Domain

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_GaussFT ( in, out, sigmas, order, truncation )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Fourier Domain implementation of a Gaussian convolution filter and Gaussian derivative convolution filters. The Gaussian kernel in the Fourier Domain is cut off at the equivalent of truncation times sigmas. If truncation is smaller or equal to 0, it is cut off where the argument to exp is smaller than -50, as in FTGaussian.

The order parameter may be zero, in which case no derivatives are taken.

ARGUMENTS

| Data type | Name | Description |
|---|------------|--|
| dip_Image | in | Input |
| ${\tt dip_Image}$ | out | Output |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| $\mathtt{dip}_{	extsf{-}}\mathtt{IntegerArray}$ | order (0) | Order of Derivative along each dimension |
| dip_float | truncation | Truncation of Gaussian kernel, see |
| | | GlobalGaussianTruncationGet |

GaussianNoise

Generate an image disturbed by Gaussian noise

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_GaussianNoise ( in, out, variance, random )
```

DATA TYPES

integer, float

FUNCTION

Generate an image disturbed by additive Gaussian noise. See GaussianRandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description |
|--------------|----------|--|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_float | variance | Variance of the Gaussian distribution the noise is drawn |
| | | from |
| dip_Random * | random | Pointer to a random value structure |

EXAMPLE

Get a image with additive Gaussian noise as follows:

```
dip_Image in, out;
dip_float variance;
dip_Random random;

variance = 1.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_GaussianNoise( in, out, variance, &random ));
```

GaussianRandomVariable

Gaussian random variable generator

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_GaussianRandomVariable ( random, mean, variance, output1,
output2 )
```

FUNCTION

GaussianRandomVariable uses the algorithm described by D.E. Knuth as the Polar Method to generate two Gaussian distributed random variables. See RandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description |
|--------------|----------|--|
| dip_Random * | random | Pointer to a random value structure |
| dip_float | mean | Mean of the distribution, the samples are drawn from |
| dip_float | variance | Variance of the distribution, the samples are drawn from |
| dip_float * | output1 | First output value |
| dip_float * | output2 | Second output value |

EXAMPLE

Get two Gaussian random variable as follows:

```
dip_Random random;
dip_float mean, variance, value1, value2;

mean = 0.0;
variance = 1.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_GaussianRandomVariable( &random, mean, variance, &value1, &value2 ));
```

GaussianSigma

Adaptive Gaussian smoothing filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_GaussianSigma ( in, out, boundary, sigma, gaussSigma,
outputCount, truncation )
```

DATA TYPES

integer, float

FUNCTION

The GaussianSigma filter is an adaptive Gauss-ian smoothing filter. The value of the pixel under investigation is replaced by the Gaussian-weighted average of the pixelvalues in the filter region which lie in the interval +/- 2 sigma from the value of the pixel that is filtered. The filter region is specified by gaussSigma and truncation. If outputCount is DIP_TRUE, the output values represent the number of pixel over which the average has been calculated. When threshold is DIP_TRUE, the pixel intensities are thresholded at +/- 2 sigma, when it is set to DIP_FALSE, the intensities are weighted with the Gaussian difference with the intensity of the center pixel.

With threshold set to DIP_FALSE, this filter is also known as the bilateral filter.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-------------|-----------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_float | sigma | Sigma |
| dip_FloatArray | gaussSigma | Sigma of Gaussian |
| dip_Boolean | outputCount | Output the Count |
| dip_float | truncation | Truncation of Gaussian, see |

GeneralConvolution

Genaral convolution filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_GeneralConvolution ( in, psf, out, boundary )
```

DATA TYPES

integer, float, complex

FUNCTION

This function convolves the in image with the point spread function psf, directly in the spatial domain. If the kernel psf is separable, use the function SeparableConvolution instead. If psf is large (and not separable), use the function ConvolveFT instead.

If the image psf is even in size, the origin is taken as the pixel to the right of the middle.

ARGUMENTS

| Data type | Name | Description |
|---|----------|---------------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | in | Input image |
| dip_Image | psf | Psf image |
| dip_Image | out | Output image |

GeneralisedKuwahara

Generalised Kuwahara filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_GeneralisedKuwahara ( in, selection, out, se, boundary, param,
shape, minimum )
```

DATA TYPES

binary, integer, float

FUNCTION

This function is a generalisation of the Kuwahara filter in the sense that is does not use the variance criterion to select the smoothed value, but instead accepts an image with the selection values. The algorithm finds, for every pixel, the minimum or maximum (as specified with minimum) value of selection within the filter window (its size specified by param), and outputs the corresponding value in in. When in is the output of Uniform, and selection is the output of VarianceFilter, this function produces the same result as Kuwahara.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-----------|-------------------------------|
| dip_Image | in | Input |
| dip_Image | selection | Selection |
| dip_Image | out | Output |
| dip_Image | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |
| dip_Boolean | minimum | Select minimum or maximum? |

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

GeneralisedKuwaharaImproved

Generalised Kuwahara filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_GeneralisedKuwaharaImproved ( in, selection, out, se, boundary,
param, shape, threshold, minimum )
```

DATA TYPES

binary, integer, float

FUNCTION

This function implements an improved version of <code>GeneralisedKuwahara</code>, see that function's description for more information. This function adds a <code>threshold</code> parameter that avoids false edges in uniform regions. If the difference between maximal and minimal values within the filter window is smaller or equal to <code>threshold</code>, the centre pixel is taken, instead of the minimum (or maximum). Setting <code>threshold</code> to zero yields the same result as <code>GeneralisedKuwahara</code>.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|--|
| dip_Image | in | Input |
| dip_Image | selection | Selection |
| dip_Image | out | Output |
| $\mathtt{dip}_{-}\mathtt{Image}$ | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |
| dip_float | threshold | Minimal value difference within window |
| dip_Boolean | minimum | Select minimum or maximum? |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

Get

Get a pixel value

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Get ( in, const, cor, adjust )
```

FUNCTION

This functions get the value of a pixel in image in at the coordinate cor. If cor is zero, the first pixel value is retrieved.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------|----------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| dip_Image | const | 0-D output image |
| dip_IntegerArray | cor | Pixel coordinate |
| dip_Boolean | adjust | Adjust data type of output image |

${\tt GetLibraryInformation}$

Support function

SYNOPSIS

```
#include "dip_information.h"
dip_Error dip_GetLibraryInformation ( info )
#include "dipio_image.h"
dip_Error dipio_GetLibraryInformation ( info )
```

FUNCTION

This function fills the given dip_LibraryInformation structure with information about the release version and date, copyright information and author information of the DIPlib library.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|------|----------------------------|
| dip_LibraryInformation* | info | DIPlib library information |

GetLine

Get a line from an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_GetLine ( in, out, cor, dimension )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Get a orthogonal line form an image. The position of the line in the image is specified by the coordinates at which its left most pixel (cor) should be placed and on which dimension of the image, the dimension of the line maps (dimension). If in has If in has a different type than out, it will be converted to the type of out.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|---|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input Image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output Line Image |
| dip_IntegerArray | cor | Coordinate in the image of the left most pixel of the |
| | | line |
| dip_int | dimension | Dimension of the image on which the line's dimension |
| | | maps |

SEE ALSO

GetMaximumAndMinimum

statistics function

SYNOPSIS

dip_Error dip_GetMaximumAndMinimum (in, mask, max, min)

DATA TYPES

 $integer,\,float\\$

FUNCTION

This function gets both the maximum and minimum of all the pixel values in the in image. Optionally, a mask image can be specified to exclude pixels from this search.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask image |
| dip_float | *max | Pointer to maximum variable |
| dip_float | *min | Pointer to minimum variable |

SEE ALSO

Maximum, Minimum

GetObjectLabels

Lists object labels in image

SYNOPSIS

dip_Error dip_GetObjectLabels (in, mask, labels, nullIsObject, resources)

DATA TYPES

binary, integer

FUNCTION

This function produces an array of object labels present in the image in. Optionally, mask can mask the regions in in where to search for labels. The boolean nullIsObject specifies whether or not to treat the value zero as an object label.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------------|--|
| dip_Image | in | Input label image |
| dip_Image | mask | Mask image |
| dip_IntegerArray * | labels | Array of labels |
| dip_Boolean | nullIsObject | treat the value zero ad an object label |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

Label, IntegerArrayFind

GetRank

Value selection function

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_GetRank ( array, datatype, min, max, rank, value )
```

FUNCTION

GetRank gets the value at rank rank in the array array. min should be set to the first index of array, max to the last. dip_GetRank will use array for temporary storage, so the values in the array will be changed are this function is ready.

ARGUMENTS

| Data type | Name | Description |
|--------------|----------|---------------------------|
| dip_float * | array | Array to searched in |
| dip_DataType | datatype | |
| dip_int | min | minimal array index |
| dip_int | max | maximal array index |
| dip_int | rank | Rank |
| dip_float * | value | Value of the rank element |

EXAMPLE

This example finds the median value for the array.

```
dip_float array[ SIZE ], median;
dip_int rank;

/* fill the array with values */

rank = SIZE/2;
DIPXX( dip_GetRank( array, DIP_DT_FLOAT, 0, (SIZE - 1), rank, &median ));
```

GetSlice

Get a slice from an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_GetSlice ( in, out, cor, dim1, dim2 )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Get a orthogonal slice from a image. The requested slice is selected by specifying its upper left corner (cor) and on which dimensions of the image, the dimensions of the slice map (dim1, dim2). If in has a different type than out, it will be converted to the type of out.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|---|
| dip_Image | in | 3D Input Image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | 2D Output Image |
| dip_IntegerArray | cor | Coordinate in in of the upper left corner of the slice |
| dip_int | dim1 | Dimension of in on which the slice's first dimension maps |
| dip_int | dim2 | Dimension of in on which the slice's second |
| | | dimensionmaps |

GetUniqueNumber

Obtain an unique value

297

SYNOPSIS

```
#include "dip_globals.h"
dip_Error dip_GetUniqueNumber ( number )
```

FUNCTION

This function gives an unique integer value. The value is unique is the sense that its value has not yet been returned by this function nor will it be returned by subsequent calls.

ARGUMENTS

| Data type | Name | Description |
|-----------|--------|---|
| dip_int * | number | Pointer to an integer in which the number is stored |

${\tt Global Boundary Condition Get}$

Get global Boundary Conditions

SYNOPSIS

```
#include "dip_globals.h"
dip_Error dip_GlobalBoundaryConditionGet ( boundary, size, resources )
```

FUNCTION

This function allocates the boundary array array of size size with the global default boundary conditions for each dimension of the image. The initial values of this global array is DIP_BC_SYMMETRIC_MIRROR.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-----------|--|
| dip_BoundaryArray * | boundary | Pointer to Boundary conditions |
| dip_int | size | Size of the new array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

GlobalFilterShapeGet

Get global filter shape value

SYNOPSIS

```
#include "dip_globals.h"
dip_Error dip_GlobalFilterShapeGet ( shape )
```

FUNCTION

This function gets the global default of the filter shape used by DIPlib's linear and morphology filters. The initial value of this global is DIP_FLT_SHAPE_RECTANGULAR.

This setting currently has no effect on any of the filters in DIPlib.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-------|--------------|
| dip_FilterShape * | shape | Filter shape |

GradientDirection2D

Derivative filter

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_GradientDirection2D ( in, out, boundary, ps, sigmas, tc,
atanFlavour, flavour )
```

DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float**

FUNCTION

Computes the gradient direction of an image using the <code>Derivative</code> function. This functions supports only two dimensional images.

ARGUMENTS

| Data type | Name | Description |
|--|-------------|-----------------------------|
| ${\tt dip_Image}$ | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | ps | Dimensions to process |

Greater

Compare grey values in two images

SYNOPSIS

dip_Error dip_Greater (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function sets each pixel in out to "true" when for corresponding pixels in1 > in2. This is the same as Compare with the DIP_SELECT_GREATER selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

ARGUMENTS

| Data type | Name | Description |
|--------------------|------|--------------|
| ${\tt dip_Image}$ | in1 | First input |
| dip_Image | in2 | Second input |
| dip_Image | out | Output |

SEE ALSO

DIP*lib* function reference 309

GreyValuesInPixelTable

Copy greyvalues from image in pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_GreyValuesInPixelTable ( table, image, ptgreyvalues, resources
)
```

DATA TYPES

integer, float

FUNCTION

This functions converts a grey-value image to a newly allocated floating-point array, in which each element is the grey value associated to a pixel in the pixel table. The image must have the same size and dimensionality as the pixel table's bounding box. For example:

```
dip_Image kernel, binkernel;
dip_PixelTable table;
dip_FloatArray values;
...
dip_NotZero( kernel, binkernel );
dip_BinaryImageToPixelTable( binkernel, &table, resources );
dip_GreyValuesInPixelTable( table, kernel, &values, resources );
...
process->filter->array[0].parameters = values;
dip_PixelTableFrameWork( in, out, boundary, process, table );
```

ARGUMENTS

| Data type | Name | Description | |
|-------------------------------|-----------|--|--|
| dip_PixelTable | table | Pixel table | |
| dip_Image | image | Grey-value image | |
| dip_FloatArray * ptgreyvalues | | Array to which to write pixel grey values | |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew | |

${\tt GreyWeightedDistanceTransform}$

Grey weighted distance transform

SYNOPSIS

```
#include "dip_distance.h"
dip_Error dip_GreyWeightedDistanceTransform ( in, seed, out, distance, chamfer, neighborhood, metric )
```

DATA TYPES

in: integer, float
seed: binary

FUNCTION

GreyWeightedDistanceTransform determines the grey weighted distance transform of the object elements in the in image and returns the result in the out image. The implemented algorithm uses a heap sort for sorting the pixels to be processed.

The images in and seed must have the same dimensions. The out image will be converted to a sfloat typed image. The seed image defines the elements that are part of the object for which the GDT is determined. It can be any type of image where all image elements not equal to 0 are considered to be part of the object(s). Those elements that are neighboring an object element in the output image are considered seeds. Before any seeds are detected the borders of the out image are set to 0. The size of the border is determined by the chamfer metric size (see below). In case of a 3 by 3 chamfer metric the image border is one element, in case of a 5 by 5 chamfer it is 2 elements. Elements in the border are not considered seeds. If no valid seeds are found the routine will terminate with an Illegal value error code.

The chamfer metric is defined by two parameters: neighborhood and metric. neighborhood should supply the different relative addresses of the neighboring elements according to the chamfer metric. The first element neighborhood[0] contains the number of elements in the chamfer neighborhood. The next three elements contain the maximum number of elements a chamfer metric exceeds the central element. The rest of the elements (starting from the fifth element) contain addresses of the different chamfer elements relative to the central element. The metric array contains the corresponding chamfer metric value. An example of a 3x3 neighborhood array with the corresponding metric is:

```
neighborhood[0] = 8 (number of elements)
neighborhood[1] = 1 (x-border size)
neighborhood[2] = 1 (y-border size)
```

```
neighborhood[3] = 0 (z-border size)
neighborhood[4] = -imagewidth - 1,
                                      metric[0] = 7
neighborhood[5] = -imagewidth,
                                      metric[1] = 5
                                      metric[2] = 7
neighborhood[6] = -imagewidth + 1,
neighborhood[7] = -1,
                                      metric[3] = 5
neighborhood[8] = 1,
                                      metric[4] = 5
neighborhood[9] = imagewidth - 1,
                                      metric[5] = 7
neighborhood[10] = imagewidth,
                                      metric[6] = 5
                                      metric[7] = 7
neighborhood[11] = imagewidth + 1,
```

where imagewidth represents the width of the image in image pixels. If both neighborhood and metric pointers are NULL, the chamfer variable can be set to either 1 (indicating a 3x3 or 3x3x3 chamfer using only 4 or 6 direct neighbors), 3 (indicating a 3x3 or 3x3x3 chamfer, using all neighbors) or 5 (indicating a 5x5 or 5x5x5 chamfer). In these cases a preset neighborhood and metric arrays will be used.

ARGUMENTS

| Data type | Name | Description | |
|----------------------------------|--------------|--|--|
| dip_Image | in | Input image | |
| dip_Image | seed | Seed image | |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Integrated grey-value over least-resistance path | |
| | | (output image) | |
| $dip_{-}Image$ | distance | Metric distance over least-resistance path (output | |
| | | image) | |
| dip_int | chamfer | Chamfer distance metric | |
| dip_IntegerArray | neighborhood | Neighborhood | |
| dip_FloatArray | metric | Metric | |

KNOWN BUGS

GreyWeightedDistanceTransform works only on 2 or 3-dimensional images. It will not work if any of the images has different strides.

GreyWeightedDistanceTransform produces incomplete results in a 2-pixel border around the edge (4 for chamfer = 5). If this is an issue, consider adding 2 pixels on each side of your image. Make sure that in has high grey values in the border to avoid unexpected output.

The function **GrowRegionsWeighted** produces a grey-weighted distance transform without these limitations and with some other possibilities.

GrowRegions

Dilate the regions in a labelled image

SYNOPSIS

```
#include "dip_regions.h"
dip_Error dip_GrowRegions ( in, grey, mask, out, connectivity, iterations,
order )
```

DATA TYPES

in: binary, integer

grey: interger, float (converted to dip_sfloat)

mask: dip_uint8

FUNCTION

The regions in the input image in are grown with several options:

If grey is NULL, the regions are dilated iterations steps, according to connectivity (see The connectivity parameter), and optionally constrained by mask. This is the labelled equivalent to BinaryPropagation. If iterations is 0, the objects are dilated until no further change is possible. order is ignored.

If an image grey is given, the labels are grown in order of the grey-values in grey. order indicates whether pixels with high grey-values are added first or last. iterations is ignored, and mask is an optional constraint. This is a watershed algorithm with initial labels. The function Watershed does not accept an initial segmentation, so these two functions complement each other. Note that GrowRegions does not leave any watershed pixels in between the regions.

ARGUMENTS

| Data type Name | | Description | |
|-------------------------|--------------|--|--|
| dip_Image | in | Input binary or labelled image | |
| dip_Image | grey | Input grey-value image | |
| dip_Image | mask | Mask image | |
| dip_Image | out | Output binary or labelled image | |
| dip_int | connectivity | Connectivity | |
| dip_int | iterations | Number of iterations | |
| dipf_GreyValueSortOrder | order | Whether to grow from low to high or high | |
| | | to low | |

The ${\tt dipf_GreyValueSortOrder}$ enumeration consists of the following values:

| Name | Description |
|---------------------|--|
| DIP_GVSO_HIGH_FIRST | Process the pixels from high grey-value to low grey-value. |
| DIP_GVSO_LOW_FIRST | Process the pixels from low grey-value to high grey-value. |

GrowRegionsWeighted, Watershed, BinaryPropagation, Label

GrowRegionsWeighted

Grow labelled regions using grey-weighted distances

SYNOPSIS

```
#include "dip_regions.h"
dip_Error GrowRegionsWeighted ( in, grey, mask, out, distance, pixelsize, chamfer, metric )
```

DATA TYPES

in: binary, integer

grey: interger, float (converted to dip_sfloat)

mask: dip_uint8

FUNCTION

The regions in the input image in are grown according to a grey-weighted distance metric; the weights are given by grey. The optional mask image mask limits the growing. out contains the grown regions, and distance, if not 0, contains the grey-weighted distance of each pixel in mask to the nearest pixel in in. Non-isotropic sampling is supported through pixelsize, which can be set to 0 to assume isotropic sampling. chamfer selects the size of the chamfer metric: 3 or 5. Set chamfer to 0 to use a custom metric given by the image metric. This image should be odd in size, and each pixel gives the distance to the center pixel. The pixels set to 0 will not be considered as neighbors.

The chamfer metric used is the following for chamfer==3 (with ps0=pixelsize->array[0] and ps1=pixelsize->array[1]):

| sqrt(ps0*ps0+ps1*ps1) | ps1 | sqrt(ps0*ps0+ps1*ps1) |
|-----------------------|-----|-----------------------|
| ps0 | 0 | ps0 |
| sqrt(ps0*ps0+ps1*ps1) | ps1 | sqrt(ps0*ps0+ps1*ps1) |

and the following for chamfer==5:

| 0 | | 0 | | 0 | |
|---|--------------------------|-----------|----------------|--|-----------|
| | sqrt(ps0*ps0+4 | *ps1*ps1) | sqrt(ps0*ps0+4 | *ps1*ps1) | |
| | | ps1 | | | |
| sqrt(4*ps0*ps0 | +pssq1r*tp(sp1s)0*ps0+p; | s1*ps1) | sqrt(ps0*ps0+p | s <i>1stpst10</i> 4*ps0*ps0 | +ps1*ps1) |
| 0 | ps0 | 0 | ps0 | 0 | |
| | | ps1 | | | |
| sqrt(4*ps0*ps0+pss/r*p(sps))*ps0+ps1*ps1) | | | sqrt(ps0*ps0+p | s <i>1st</i> ps t104*ps0*ps0 | +ps1*ps1) |
| 0 | | 0 | | 0 | |
| | sqrt(ps0*ps0+4 | *ps1*ps1) | sqrt(ps0*ps0+4 | *ps1*ps1) | |

Setting chamfer to 0 and metric to an image with these values produces the same results as setting chamfer to 3 or 5.

The output image distance is comparable to the out image of GreyWeightedDistanceTransform, except that that function uses optimal chamfer distances whereas this one uses the (sub-optimal) true distance. In return, this function works on images of any dimensionality, allows for non-isotropic sampling, does not skip pixels close to the edge of the image, and can be used with a mask image to constrain the propagation. Note that the seed image in GreyWeightedDistanceTransform corresponds to the zero pixels of in for this function.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|---------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input binary or labelled image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | grey | Input grey-value image |
| dip_Image | mask | Mask image |
| dip_Image | out | Output binary or labelled image |
| dip_Image | distance | Output distance image |
| dip_FloatArray | pixelsize | Pixel size |
| dip_int | chamfer | Chamfer distance |
| dip_Image | metric | Custom metric |

HartleyTransform

Computes the Hartley transform

SYNOPSIS

```
#include "dip_transform.h"
dip_Error dip_HartleyTransform ( in, out, trFlags, process )
```

DATA TYPES

binary, integer, float

FUNCTION

This function computes a Hartley transform on in and places the result in out.

Normalisation: 1/sqrt(dimension) for each dimension.

The main advantage of the Hartley transform over the Fourier transform is that is requires half the storage for real valued images. Note, that is also possible to directly reduce the storage requirements of the Fourier transform by just storing the right half plane, since for real valued images the left half plane can be derived from the right half using the symmetry properties of the Fourier transform.

Unfortunately there seem to be two definitions of the multi-dimensional Hartley transform (they are identical in the 1-D case). DIPlib implements the Bracewell (see below) variant, since this one is easy to implement and inherits the storage advantage from the 1-D case. The following are references which each use a different variant (all scaling factors have been dropped):

Bracewell, "Discrete Hartley Transform", J. Opt. Soc. Am, vol. 73, no. 12, December 1983:

$$DHT(u,v) = Sum Sum I(x,y) cas(ux) cas(vy)$$

$$y x$$

Kenneth R. Castleman, "Digital image processing", Prentice Hall, 1996:

$$DHT(u,v) = Sum Sum I(x,y) cas(ux + vy)$$

$$y x$$

Using cas(a) = cos(a) + sin(a):

cas(ux)cas(vy) = cos(ux)cos(vy)+cos(ux)sin(vy)+sin(ux)cos(vy)+sin(ux)sin(vy)

$$cas(ux+vy) = cos(ux)cos(vy)+cos(ux)sin(vy)+sin(ux)cos(vy)-sin(ux)sin(vy)$$

319

A subtle difference. The two definitions have very similar properties, for example the convolution property.

In implementation terms, Bracewell is equivalent to perform the one-dimensional Hartley transform along each dimension. The Castleman variant is equivalent to the definition: DHT = re(DFT) - im(DFT). On a final note, I've not noticed mention of the difference between the two variants, so the indications Bracewell's and Castleman's variant are not and should not be accepted "labels" to refer to the variants (For both variants I have selected the first reference I came across, not chronologically the first reference to use the variant).

Defaults: process may be zero, indicating that all dimensions should be processed.

ARGUMENTS

| Data type | Name | Description |
|-------------------------------|------|-----------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dipf_FourierTransform trFlags | | Transformation flags |
| dip_BooleanArray process (0) | | Dimensions to process |

The dipf_FourierTransform enumeration consists of the following flags:

| Name | Description |
|----------------|------------------------|
| DIP_TR_FORWARD | Forward transformation |
| DIP_TR_INVERSE | Inverse transformation |

FourierTransform

HasContiguousData

Determines whether an image has all data contiguous in memory

SYNOPSIS

dip_Error dip_HasContiguousData(image, &answer)

FUNCTION

Determines whether an image has all data contiguous in memory. This can potentially not be the case if the image is an ROI, for example, or if it was allocated with strides that cause unused gaps in the image's memory block. If answer is not zero, the verdict is passed in this variable. Otherwise, HasContiguousData returns an error in case image does not have contiguous data.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------|-------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | image | The image under investigation |
| dip_Boolean * | answer | The verdict |

SEE ALSO

The image structure

HasNormalStride, ImageGetStride, IsScalar

HasNormalStride

Determines whether an image has a normal stride

SYNOPSIS

dip_Error dip_HasNormalStride(image, &answer)

FUNCTION

Determines whether an image has a normal stride. Normal stride is defined as a stride of 1 in the first dimension, a stride of image width in the second dimension, etc. If answer is not zero, the verdict is passed in this variable. Otherwise, HasNormalStride returns an error in case image does not have a normal stride.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------|-------------------------------|
| ${\tt dip_Image}$ | image | The image under investigation |
| dip_Boolean * | answer | The verdict |

${\tt HysteresisThreshold}$

Point Operation

SYNOPSIS

```
#include "dip_point.h"
dip_Error dip_HysteresisThreshold ( in, out, low, high )
```

DATA TYPES

integer, float

FUNCTION

Performs hysteresis thresholding. From the binary image (in>low) only those regions are selected for which at least one location also has (in>high). The output image will be a binary image with foreground pixel 1 and background pixel 0;

ARGUMENTS

| Data type | Name | Description |
|--------------------|------|------------------|
| ${\tt dip_Image}$ | in | Input image |
| dip_Image | out | Output image |
| dip_float | low | Lower threshold |
| dip_float | high | Higher threshold |

SEE ALSO

Threshold, RangeThreshold, IsodataThreshold

IDivergence

difference measure

SYNOPSIS

dip_Error dip_IDivergence (in1, in2, mask, out)

DATA TYPES

binary, integer, **float**

FUNCTION

Calculates the I-divergence between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

The I-Divergence is defined as: $I(x,y) = x \ln(x/y) - (x - y)$ and is divided by the number of pixels. It is the -log of a possion distribution $p(x,y)=e^{-(-y)/x!-y^x}$ with the stirling approximation for $\ln x!$. For x=0, the stirling approximation would fail, y is returned.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input, Data:x |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input, Model:y |
| dip_Image | mask | Mask |
| dip_Image | out | Output |

ImageAssimilate

Inherit properties of another image

SYNOPSIS

dip_Error dip_ImageAssimilate(example, target)

FUNCTION

Give the target image the same properties (type, data type, etc...) as the example image. The example image may be either "raw" or "forged". The target image is forged.

If the target was forged before calling this function, and it exactly matches the example, nothing happens. If it doesn't match the example, it is stripped before the properties are copied.

ARGUMENTS

| Data type | Name | Description |
|---|---------|------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | example | An example image |
| ${\tt dip_Image}$ | target | The target image |

ImageChainCode

Extracts all chain codes from a labeled image

SYNOPSIS

```
#include "dip_chaincode.h"
dip_Error dip_ImageChainCode ( objectIm, connectivity, objectID, chaincodearray, resources )
```

DATA TYPES

integer

FUNCTION

Extracts the chain codes for the objects in objectIm (only 2D images supported) that are listed in objectID, assuming that each object is compact (i.e. it returns the chain code for only one border for each label ID in objectID). Chain codes are constructed according to connectivity, which can only be 1 or 2 (see The connectivity parameter). The output structure chaincodearray is allocated by this function and registered in resources.

The dip_ChainCodeArray structure, like all arrays in DIPlib, contains a size and an array element. Each element is of type dip_ChainCode, and accessed by chaincodearray->array[ii], where ii is between 0 and chaincodearray->size-1. Data in the dip_ChainCode structures can only be accessed through the corresponding access functions, see ChainCodeNew.

ARGUMENTS

| Data type | Name | Description |
|----------------------|----------------|--------------------------------------|
| dip_Image | objectIm | Labeled input image |
| dip_int | connectivity | Pixel connectivity of the objects |
| dip_IntegerArray | objectID | Array containing object label values |
| dip_ChainCodeArray * | chaincodearray | Output chain codes |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

The image structure

ImageFileGetInfo

Get information about image in file (in dipIO)

SYNOPSIS

dip_Error dipio_ImageFileGetInfo (imInfo, filename, format, addExtensions, recognised, resources)

FUNCTION

This function opens an image file and fills a dipio_ImageFileInformation structure with the information from that file. imInfo is allocated by this function. Use ImageFileInformationFree to free this structure, or set the resources parameter for automatic deallocation. If format is 0, all different ImageRead functions are called in sequence until the correct format has been found. If you know the format, get the correct format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats.

The boolean addExtensions specifies whether ImageFileGetInfo should try to add file format extensions to filename, if the registered file format reader fails to recognise filename straight away. The extensions are provided by the registered file readers.

If recognised is not zero, ImageFileGetInfo will set it to DIP_TRUE when it has been able to read filename, and it will set it to DIP_FALSE when it is not able to read the file. No error will be generated in this case.

ARGUMENTS

| Data type | Name | Description |
|------------------------------|---------------|------------------------------------|
| dipio_ImageFileInformation * | imInfo | Output image file information. See |
| | | ImageFileInformationNew |
| dip_String | filename | File name |
| dip_int | format | ID of file format |
| dip_Boolean | addExtensions | Add file format extensions to |
| | | filename |
| dip_Boolean * | recognised | Pointer to boolean containing the |
| | | file read status |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

DIP*lib* function reference 337

${\tt ImageFileInformationFree}$

Free a Image File Information structure (in dipIO)

SYNOPSIS

dip_Error dipio_ImageFileInformationFree (imInfo)

FUNCTION

Frees a dipio_ImageFileInformation structure allocated through ImageFileInformationNew or by ImageFileGetInfo.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------------|--------|-------------------|
| ${	t dipio_ImageFileInformation} *$ | imInfo | Structure to free |

SEE ALSO

 ${\tt ImageFileInformationNew, ImageFileGetInfo}$

ImageFileInformationNew

Allocate an Image File Information structure (in dipIO)

SYNOPSIS

dip_Error dipio_ImageFileInformationNew (newImInfo, name, filetype,
datatype, dims, resources)

FUNCTION

Allocates a dipio_ImageFileInformation structure. It must be freed through ImageFileInformationFree, unless a resources parameter is given, in which case it will be freed automatically when freeing the resources. This structure is usually allocated by ImageFileGetInfo.

This function will fill out some of the values in the structure with the values given on the command line. All of these can be 0.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------------|-----------|-----------------------------------|
| ${\tt dipio_ImageFileInformation} *$ | newImInfo | Output structure |
| dip_String | name | Initial value for name |
| dip_String | filetype | Initial value for filetype |
| dip_DataType | datatype | Initial value for datatype |
| dip_IntegerArray | dims | Initial value for dimensions |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

The structure dipio_ImageFileInformation contains the following elements:

| Data type | Name | Description |
|---------------------------------|----------------|---------------------------------|
| dip_String | name | File name |
| dip_String | filetype | File format string |
| dip_DataType | datatype | Data type of image |
| dip_int | sigbits | Significant bits |
| dip_IntegerArray | dimensions | Dimensions of image |
| dipio_PhotometricInterpretation | photometric | Color space |
| dip_PhysicalDimensions | physDims | Physical dimensions structure. |
| | | See PhysicalDimensionsNew |
| dip_int | numberOfImages | Number of images in a TIFF |
| | | file. If filetype is not |
| | | "TIFF", this number is not set |
| dip_StringArray | history | History tags |
| dip_Resources | resources | Resource tracking; all elements |
| | | within this structure are |
| | | tracked here |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

Most file formats support only some of these.

ImageForge

Allocate pixel data for an image

SYNOPSIS

dip_Error dip_ImageForge(image)

FUNCTION

Allocates a block of memory to store pixel data for an image. The image must be "raw", and will be "forged" afterwards. The routine will fail if the image fields do not contain a valid combination of values for the image type.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-------|--|
| ${\tt dip_Image}$ | image | The image for which the pixel data must be allocated |

SEE ALSO

The image structure

ImageNew, ImageFree, ImageStrip, ImageCopyProperties

ImageFree

Free an image

SYNOPSIS

dip_Error dip_ImageFree(image)

FUNCTION

Free any pixel data associated with the image and return all fields to their initial ("raw") state by calling <code>ImageStrip</code>. Then the image structure itself is freed. Notice that you must pass a pointer to the image instead of the image itself. This allows <code>ImageFree</code> to set your image variable to zero, preventing further use of the now freed image.

Because ImageNew accepts a resources structure to keep track of allocated images, direct calls to ImageFree should be unnecessary.

ARGUMENTS

| Data type | Name | Description |
|-------------|-------|------------------------------------|
| dip_Image * | image | A pointer to the image to be freed |

SEE ALSO

The image structure

 ${\tt ImageNew,\ ImageForge,\ ImageStrip,\ ImageCopyProperties}$

ImageGetData

Get the data pointers of a set of images

SYNOPSIS

dip_Error dip_ImageGetData(in, idp, iflags, out, odp, oflags, flags,
resources)

FUNCTION

Get the data pointers of a set of images. This function should not be called before the clean up of the previous invocation (by ResourcesFree) has been performed. Currently no clean up is required by ImageGetData, but any data pointers obtained by a previous call to this function should be considered invalid when calling this function. The iflags, oflags, and flags parameters are not used in the current version. These fields should be set to zero. The resources parameter is mandatory. Any of the image arrays' elements may be set to zero, indicating that it is to be ignored.

No functions that will possibly modify an image should be called after the call to ImageGetData and before its clean up. The proper time to call ImageGetPlane and ImageGetStride is right after the call to ImageGetData.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------------|-----------|-----------------------------------|
| dip_ImageArray | in | Array of input images |
| <pre>dip_VoidPointerArray *</pre> | idp | Returns input data pointers |
| ${\tt dipf_ImageGetDataArray}$ | iflags | Flags for input images |
| $	exttt{dip_ImageArray}$ | out | Array of output images |
| dip_VoidPointerArray * | odp | Returns output data pointers |
| ${	t dipf_ImageGetDataArray}$ | oflags | Flags for output images |
| ${	t dipf_ImageGetData}$ | flags | Flags for all images |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

${\tt ImageGetDimensionality}$

Read the dimensionality field

SYNOPSIS

dip_Error dip_ImageGetDimensionality(image, dimensionality)

FUNCTION

Read the dip_Image dimensionality field.

ARGUMENTS

| Data type | Name | Description |
|---|----------------|----------------------------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | image | An image |
| dip_int * | dimensionality | Returns the dimensionality field |

SEE ALSO

ImageGetDimensions

ImageGetDimensions

Read the dimensions array

SYNOPSIS

dip_Error dip_ImageGetDimensions(image, dimensions, resources)

FUNCTION

Read the dip_Image dimensions Array. The array that is used to return the dimensions in, is allocated by this routine using IntegerArrayNew.

ARGUMENTS

| Data type | Name | Description |
|--------------------|------------|--|
| dip_Image | image | An image |
| dip_IntegerArray * | dimensions | Returns the dimensions Array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

The image structure

 ${\tt ImageGetDimensionality}$

ImageGetPlane

Read the plane number

SYNOPSIS

dip_Error dip_ImageGetPlane(image, plane)

FUNCTION

Read the dip_Image plane number. For binary images this is the number of the bit in which the data is stored. For other data types it is meaningless. The proper time to call this function is right after ImageGetData.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-------|--------------------------|
| ${\tt dip_Image}$ | image | An image |
| dip_Int * | plane | Returns the plane number |

SEE ALSO

The image structure

 ${\tt ImageGetData, ImageGetStride}$

${\tt ImageGetStride}$

Read the stride array

SYNOPSIS

dip_Error dip_ImageGetStride(image, &stride, resources)

FUNCTION

Read the dip_Image stride array. The array that is used to return the dimensions in, is allocated by this routine using IntegerArrayNew. The proper time to call this function is right after ImageGetData.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_Image | image | An image |
| dip_IntegerArray * | stride | Returns the stride array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

ImageIsGIF

Confirm that a file is a GIF file (in dipIO)

SYNOPSIS

```
#include "dipio_gif.h"
dip_Error dipio_ImageIsGIF ( filename, veredict )
```

FUNCTION

This function verifies that the file is an GIF file. veredict is set to DIP_TRUE if it is, and to DIP_FALSE if it isn't.

ARGUMENTS

| Data type | Name | Description |
|---------------|----------|------------------------------|
| dip_String | filename | File name |
| dip_Boolean * | veredict | Set to DIP_TRUE or DIP_FALSE |

SOFTWARE

This function uses GifLib (version 4.1.0 or later), which supports GIF 87a & 98a. Copyright (c)1997 Eric S. Raymond

ImageIsTIFF

Confirm that a file is a TIFF file (in dipIO)

SYNOPSIS

```
#include "dipio_tiff.h"
dip_Error dipio_ImageIsTIFF ( filename, veredict )
```

FUNCTION

This function verifies that the file is a TIFF file. veredict is set to DIP_TRUE if it is, and to DIP_FALSE if it isn't.

ARGUMENTS

| Data type | Name | Description | |
|---------------|----------|------------------------------|--|
| dip_String | filename | File name | |
| dip_Boolean * | veredict | Set to DIP_TRUE or DIP_FALSE | |

SOFTWARE

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon Graphics, Inc.

SEE ALSO

ImageWriteTIFF, ImageReadTIFF

ImageNew

Allocate a structure

SYNOPSIS

dip_Error dip_ImageNew(image, resources)

FUNCTION

Allocates a dip_Image structure and initializes all fields to their default values. The resulting image is in the "raw" state, see The image structure. By using ImageCopyProperties and the "ImageSet" access functions, the image fields can be set to their desired values. Pixel data for the image can be allocated using the ImageForge function, which will will put the image in the "forged" state.

ARGUMENTS

| Data type | Name | Description | |
|---------------|-----------|--|--|
| dip_Image * | image | Used to return the newly allocated image | |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew | |

SEE ALSO

The image structure

ImageFree, ImageForge, ImageStrip, ImageCopyProperties

ImageRead

Read grey-value image from file (in dipIO)

SYNOPSIS

dip_Error dipio_ImageRead (image, filename, format, addExtensions,
recognised)

FUNCTION

This function reads an image from a file and puts it in image. image must be allocated before calling this function. If format is 0, all different ImageRead functions are called in sequence until the correct format has been found. If you know the format, get the correct format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats.

The boolean addExtensions specifies whether ImageRead should try to add file format extensions to filename, if the registered file format reader fails to recognise filename straight away. The extensions are provided by the registered file readers.

If recognised is not zero, ImageRead will set it to DIP_TRUE when it has been able to read filename, and it will set it to DIP_FALSE when it is not able to read the file. No error will be generated in this case.

If the file contains a colour image, Colour2Gray is called. That is, this function always returns a grey-value image.

ARGUMENTS

| Data type | Name | Description |
|---|---------------|--|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | image | Output image |
| $\mathtt{dip}_\mathtt{String}$ | filename | File name |
| $\mathtt{dip}_{-}\mathtt{int}$ | format | ID of file format |
| dip_Boolean | addExtensions | Add file format extensions to filename |
| dip_Boolean * | recognised | Pointer to boolean containing the file read status |

ImageWrite, Colour2Gray

ImageReadColour

Read colour image from file (in dipIO)

SYNOPSIS

dip_Error dipio_ImageReadColour (image, filename, photometric, format, addExtensions, recognised)

FUNCTION

This function reads an image from a file and puts it in image. image must be allocated before calling this function. It works the same as ImageRead, except that, if the file contains a colour image, Colour2Gray is not called. The returned image has an extra dimension with colours (always the last dimension), and photometric is set to the colour space.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|---------------|-------------------------------|
| $	ext{dip}_{-}	ext{Image}$ | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation* | photometric | Photometric interpretation |
| | | (==colour space) |
| dip_int | format | ID of file format |
| dip_Boolean | addExtensions | Add file format extensions to |
| | | filename |
| dip_Boolean * | recognised | Pointer to boolean containing |
| | | the file read status |

The enumerator dipio_PhotometricInterpretation contains the following constants:

DIP*lib* function reference 357

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

Most file formats support only some of these.

ImageReadGIF

Read a GIF image from file (in dipIO)

SYNOPSIS

```
#include "dipio_gif.h"
dip_Error dipio_ImageReadGIF ( image, filename, photometric )
```

FUNCTION

This function reads an image from a GIF file and puts it in image. image must be allocated before calling this function.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------------|-------------|----------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation * | photometric | Photometric interpretation |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

Most file formats support only some of these.

SOFTWARE

ImageReadICS

Read ICS image from file (in dipIO)

SYNOPSIS

```
#include "dipio_ics.h"
dip_Error dipio_ImageReadICS ( image, filename, photometric, offset, roisize,
sampling )
```

FUNCTION

This function reads the image in the ICS file and puts it in image. image must be allocated before calling this function. photometric is set to match the photometric interpretation of the data in the file, if it is recognised. The colour dimension is always the last dimension of the image (no matter how it was saved in the ICS file). offset, roisize and sampling define a ROI to read in. See the comments in ImageReadROI for more information on this.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|----------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation* | photometric | Photometric interpretation |
| dip_IntegerArray | offset | ROI offset |
| dip_IntegerArray | roisize | ROI size |
| dip_IntegerArray | sampling | ROI sampling rate |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

Most file formats support only some of these.

ImageReadJPEG

Read JPEG image from file (in dipIO)

SYNOPSIS

```
#include "dipio_jpeg.h"
dip_Error dipio_ImageReadJPEG ( image, filename, imageNumber, photometric )
```

FUNCTION

This function reads an image from the JPEG file and puts it in image. image must be allocated before calling this function. photometric is set to either DIPIO_PHM_RGB or DIPIO_PHM_GREYVALUE. If photometric is 0, the image will be read in as grey-value, even if color information is present in the file. Color images are allocated as 3D images, with the different samples along the 3rd. dimension.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------------|-------------|----------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation * | photometric | Photometric interpretation |

The enumerator ${\tt dipio_PhotometricInterpretation}$ contains the following constants:

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

ImageReadLSM

Read Zeiss LSM image from file (in dipIO)

SYNOPSIS

```
#include "dipio_lsm.h"
dip_Error dipio_ImageReadLSM ( image, filename, offset, roisize, sampling, imInfo, resources )
```

FUNCTION

This function reads the image in the Zeiss LSM file and puts it in image. image must be allocated before calling this function. Depending on the recording mode and the number of channels recorded, an image with 2 to 5 dimensions is returned. If multiple channels were recorded, they will be put along the last dimension (which can be either the third, fourth or fifth). The "stack", "time series plane" ans "time series z-scan" recording modes return a 3D image, the "time series stack" returns a 4D image, all other modes return a 2D image (including the "line" mode).

imInfo->physDims contains information on the distance between pixels. resources is only used to allocate the imInfo structure, so if imInfo is 0, resources can be 0 too.

offset, roisize and sampling define a region of interest to read in. See the comments in ImageReadROI for more information on this. Note that the channel dimension is part of this ROI.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------|-----------|-----------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dip_IntegerArray | offset | ROI offset |
| dip_IntegerArray | roisize | ROI size |
| dip_IntegerArray | sampling | ROI sampling rate |

ImageReadPIC

Read BioRad PIC image from file (in dipIO)

SYNOPSIS

```
#include "dipio_pic.h"
dip_Error dipio_ImageReadPIC ( image, filename, offset, roisize, sampling, info, resources )
```

FUNCTION

This function reads the image in the BioRAD PIC file and puts it in image. image must be allocated before calling this function. The information stored in the file is put in info.

offset and roisize define a region of interest to be read in. The ROI is clipped to the actual image data, so it is safe to specify a ROI that is too large. sampling can be used to read in a subset of the pixels of the chosen ROI. Any or all of these three parameters can be NULL.

ARGUMENTS

| Data type | Name | Description |
|------------------------------|-----------|-----------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dip_IntegerArray | offset | ROI offset |

ImageReadROI

Read a portion of a grey-value image from file (in dipIO)

SYNOPSIS

dip_Error dipio_ImageReadROI (image, filename, offset, roisize, sampling, format, addExtensions, recognised)

FUNCTION

This function reads an image from a file and puts it in image. image must be allocated before calling this function. It works the same as ImageRead, except that the user is allowed to specify a region of the image to read. This is done through the offset and roisize parameters. The ROI is clipped to the image size, so it is safe to specify a ROI that is too large. sampling can be used to read in a subset of the pixels of the chosen ROI. Any or all of these three parameters can be NULL.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|---------------|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | image | Output image |
| dip_String | filename | File name |
| dip_IntegerArray | offset | ROI offset |
| dip_IntegerArray | roisize | ROI size |
| dip_IntegerArray | sampling | ROI sampling rate |
| $\mathtt{dip}_{-}\mathtt{int}$ | format | ID of file format |
| dip_Boolean | addExtensions | Add file format extensions to filename |
| dip_Boolean * | recognised | Pointer to boolean containing the file read status |

ImageReadTIFF

Read TIFF image from file (in dipIO)

SYNOPSIS

```
#include "dipio_tiff.h"
dip_Error dipio_ImageReadTIFF ( image, filename, imageNumber, photometric )
```

FUNCTION

This function reads an image from the TIFF file and puts it in image. image must be allocated before calling this function. imageNumber indicates which image from the multi-page TIFF file to read. 0 is the first image. photometric is set to match the photometric interpretation of the TIFF file. Colour images and multi-sample images are allocated as 3D images, with the different samples along the 3rd dimension.

Multi-page TIFF files in which all pages contain an image of the same size and type, can be read as a 3D or 4D (Colour along the 4th dimension) image by setting <code>imageNumber</code> to -1. If the images are not of the same size and type, an error will be generated.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------------|-------------|----------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dip_int | imageNumber | Image number to read |
| dipio_PhotometricInterpretation * | photometric | Photometric interpretation |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|---|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, |
| | yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* |
| | and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* |
| | and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and |
| | value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and |
| | value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as |
| | DIPIO_PHM_CMYK |

Most file formats support only some of these.

SOFTWARE

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon Graphics, Inc.

This function uses zlib (version 1.1.4 or later). Copyright (c)1995-2002 Jean-loup Gailly and Mark Adler

KNOWN BUGS

TIFF is a very flexible file format. We have to limit the types of images that can be read to the more common ones, and to the ones dipIO writes. These are the most obvious limitations:

Tiled images are not supported.

Only 1, 4, 8, 16 and 32 bits per pixel integer grayvalues are read, as well as 32-bit and 64-bit floating point.

Only 4 and 8 bits per pixel colourmapped images are read. Colourmapped images contain 16-bit gray-values: stretching of the display will be necessary.

Class Y images (YCbCr) and Log-compressed images (LogLuv or LogL) are not supported.

SEE ALSO

${\tt ImageReadTIFFInfo}$

Get information about image in TIFF file (in dipIO)

SYNOPSIS

```
#include "dipio_tiff.h"
dip_Error dipio_ImageReadTIFFInfo ( imInfo, filename, imageNumber )
```

FUNCTION

Opens a TIFF file and fills a dipio_ImageFileInformation structure with the information from that file. imInfo must be allocated before calling this function. imageNumber indicates which image from the multi-page TIFF file to get info on. 0 is the first image. imInfo->numberOfImages gives the number of pages in the file.

ARGUMENTS

| Data type | Name | Description |
|----------------------------|-------------|------------------------------------|
| dipio_ImageFileInformation | imInfo | Output image file information. See |
| | | ImageFileInformationNew |
| dip_String | filename | File name |
| dip_int | imageNumber | Image number to query |

ImagesCheck

Check properties of several images

SYNOPSIS

dip_Error dip_ImagesCheck(images, imageType, dataType, compareFlag, checkFlag)

FUNCTION

This function checks whether the image type and the data type of the first image in the array matches with the imageType and dataType variables, and compares the other image fields of the first image with those of the other images in the array. This comparison is done by calling ImagesCompareTwo. The checkFlag can be used to compare properties not supported by ImagesCompare. An error is returned by ImagesCheck if a check or comparison fails.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-------------|--|
| dip_ImageArray * | images | Array of Images |
| ${\tt dip_ImageType}$ | imageType | Image type of the first Image |
| dip_DataTypeProperties | dataType | Data type of the first Image. See |
| | | DataTypeGetInfo |
| dipf_ImagesCompare | compareFlag | Properties to compare. See ImagesCompare |
| dipf_ImagesCheck | checkFlag | Extra properties to be compared |

dipf_ImagesCheck

| Name | Description |
|---------------------------------|---|
| DIP_CKIM_MAX_PRECISION_MATCH | Check whether data types match or match to the |
| | DIP_GTP_MAX_PRECISION DataType |
| DIP_CKIM_CASTING_TYPE_MATCH | Check whether data types match or match to the |
| | DIP_GTP_CAST_R2C or DIP_GTP_CAST_C2R types of |
| | the first image in image |
| DIP_CKIM_IGNORE_NULL_DIM_IMAGES | Ignore images with a zero dimensionality, this flag |
| | is usefull when 0d images are used as generic data |
| | containers of constants |

ImagesCheckTwo

Check properties of two images

SYNOPSIS

dip_Error dip_ImagesCheckTwo(image1, image2, imageType, dataType, compareFlag, checkFlag)

FUNCTION

This function checks whether the image type and the data type of the first DIPlib Image matches with the imageType and dataType variables, and compares the other Image fields of the first DIPlib Image with those of the second Image. This comparison is done by calling ImagesCompareTwo. The checkFlag can be used to compare properties not supported by ImagesCompare. ImagesCheckTwo returns an error code if a check or comparison fails.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|--|
| $dip_{-}Image$ | image1 | First Image |
| dip_Image | image2 | Second Image |
| dip_ImageType | imageType | Image type of the first Image |
| dip_DataTypeProperties dataType | | Data type of the first Image. See |
| | | DataTypeGetInfo |
| dipf_ImagesCompare | compareFlag | Properties to compare. See ImagesCompare |
| ${	t dipf_ImagesCheck}$ | checkFlag | Extra properties to be compared |

dipf_ImagesCheck

| Name | Description |
|---------------------------------|---|
| DIP_CKIM_MAX_PRECISION_MATCH | Check whether data types match or match to the |
| | DIP_GTP_MAX_PRECISION DataType |
| DIP_CKIM_CASTING_TYPE_MATCH | Check whether data types match or match to the |
| | DIP_GTP_CAST_R2C or DIP_GTP_CAST_C2R types |
| DIP_CKIM_IGNORE_NULL_DIM_IMAGES | Ignore images with a zero dimensionality, this flag |
| | is usefull when 0d images are used as generic data |
| | containers of constants |

ImagesCompare

Compare properties of several images

SYNOPSIS

dip_Error dip_ImagesCompare(images, condition, result)

FUNCTION

This function compares some standard fields of a number of Images or performs a full comparison. Only if the comparison result is true between each of the Images, will the final comparison result be true. The condition parameter specifies which properties should be tested. If 0, a full comparison of the Images is performed. Otherwise it should be a logical OR of the dipf_ImagesCompare flags. DIP_CPIM_MATCH_ALL_STANDARD is equivalent to all the flags OR'ed together. The difference between DIP_CPIM_MATCH_ALL_STANDARD and the full comparison specified by 0, is that the first will compare all the standard fields (type, data type, dimensions), whereas the other compares all fields relevant to a particular DIPlib Image type. This may exclude some of the standard fields and include some fields particular to the type of DIPlib Image in question. There are two modes of operation. If the result parameter is set, it is used to store the result of the comparison, a set of OR'ed dipf_ImagesCompare flags. If the result parameter is 0, an error is returned if the condition parameter and the resulting set of flags are not the same.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|------------------------|--|
| $	exttt{dip_ImageArray}$ | images Array of Images | |
| dipf_ImagesCompare | condition | Properties to compare. 0 indicates full |
| | | comparison |
| dipf_ImagesCompare * | result | Result: flags to indicate if the properties were the |
| | | same. 0 indicates that an error should be |
| | | returned if the requested properties do not match |

$dipf_ImagesCompare$

| Name | Description |
|---------------------------------|---|
| DIP_CPIM_DIMENSIONALITIES_MATCH | Dimensionalities match |
| DIP_CPIM_DIMENSIONS_MATCH | Dimensions match. The comparison is done up to |
| | the lower of the of the two dimensionalities |
| DIP_CPIM_SIZE_MATCH | Combination of |
| | DIP_CPIM_DIMENSIONALITIES_MATCH and |
| | DIP_CPIM_DIMENSIONS_MATCH |
| DIP_CPIM_TYPES_MATCH | Types match |
| DIP_CPIM_DATA_TYPES_MATCH | Data types match |
| DIP_CPIM_MATCH_ALL_STANDARD | All flags above OR'ed together |
| DIP_CPIM_STRIDES_MATCH | Strides match |
| DIP_CPIM_FULL_MATCH | Full match. Returned in result. To test for a full |
| | match use 0. Note: This is NOT equivalent to the |
| | other flags OR'ed together, and it cannot be used |
| | as condition |

ImagesCompareTwo

Compare properties of two images

SYNOPSIS

dip_Error dip_ImagesCompareTwo(image1, image2, condition, result)

FUNCTION

This function compares some standard fields of two Images or performs a full comparison. The condition parameter specifies which properties should be tested. See ImagesCompare for more information. There are two modes of operation. If the result parameter is set, it is used to store the result of the comparison, a set of OR'ed dipf_ImagesCompare flags. If the result parameter is 0, an error is returned if the condition parameter and the resulting set of flags are not the same.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------|-----------|--|
| dip_Image | image1 | First Image |
| dip_Image | image2 | Second Image |
| ${\tt dipf_ImagesCompare}$ | condition | Properties to compare. See ImagesCompare |
| dipf_ImagesCompare* | result | Result: flags to indicate if the properties were the |
| | | same. 0 indicates that an error should be returned |
| | | if the requested properties do not match |

ImageSetType

Set the image type field

SYNOPSIS

dip_Error dip_ImageSetType(image, type)

FUNCTION

Set the dip_Image type field. The image must be "raw".

ARGUMENTS

| Data type | Name | Description |
|---|-------|----------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | image | An image |
| $\mathtt{dip}_{-}\mathtt{ImageType}$ | type | The image type |

SEE ALSO

The image structure ImageGetType

${\tt ImageSort}$

Sort image data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_ImageSort ( in, out, algorithm )
```

FUNCTION

Produces an image (out) with the sorted pixel values of in.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|----------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_Sort | algorithm | Sort algorithm |

The sortType parameter is one of:

| Name | Description |
|----------------------------|------------------------|
| DIP_SORT_DEFAULT | Default sort algorithm |
| DIP_SORT_QUICK_SORT | Quick sort |
| DIP_SORT_DISTRIBUTION_SORT | Distribution sort |
| DIP_SORT_INSERTION_SORT | Insertion sort |

SEE ALSO

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, SortIndices, SortIndices16, ImageSortIndices}$

${\tt ImageSortIndices}$

Sort indices to image data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_ImageSortIndices ( in, indices, algorithm, flags )
```

FUNCTION

Sorts a list of indices rather than the data itself using the algorithm specified by algorithm. Unless the DIP_ISI_USE_INDICES, the indices image will be initialised with one index for each pixel in the image.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-----------|----------------|
| dip_Image | in | Input |
| dip_Image | indices | Indices |
| dip_Sort | algorithm | Sort algorithm |
| ${	t dipf_{-}ImageSortIndices}$ | flags | Flags |

The sortType parameter is one of:

| Name | Description |
|----------------------------|------------------------|
| DIP_SORT_DEFAULT | Default sort algorithm |
| DIP_SORT_QUICK_SORT | Quick sort |
| DIP_SORT_DISTRIBUTION_SORT | Distribution sort |
| DIP_SORT_INSERTION_SORT | Insertion sort |

The dipf_ImageSortIndices enumeration consists of the following flags:

| Name | Description |
|---------------------|---|
| DIP_ISI_USE_INDICES | Use the indices as given in the indices image |

SEE ALSO

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, ImageSort, SortIndices, SortIndices16}$

ImagesSeparate

Take care of in-place operations

SYNOPSIS

dip_Error dip_ImagesSeparate(in, out, newOut, saved, resources)

FUNCTION

First the list of output images is checked to see if any output image is used more than once. If this is the case an error is returned. Then the input and output images are examined. If any of the output images is also used as an input image, the function allocates a new image. This image is returned through the newOut array. For each output image a corresponding image is returned in this array. Either the original output image itself, or either a new image as discussed above. After the call to dip_ImagesSeparate, the images in the newOut array should be used instead of the original output images. After you are done processing the images, a call to ResourcesFree will perform the necessary post-processing. The post-processing consists of copying the data from the temporary output images to the original output images and freeing the temporary images. Because the post-processing is called through ResourcesFree, the resources parameter is mandatory. Any of the image arrays' elements may be set to zero, indicating that it is to be ignored.

The boolean saved array can be used to indicate that an input image has been stored in a safe place. In this case dip_ImagesSeparate will not have to allocate a temporary image if the input image is also used as an output image. The saved parameter may either be zero, which indicates that none of the input images has been saved, or it must be an array containing booleans corresponding each of the input images. DIP_TRUE indicates that the image has been saved.

ARGUMENTS

| Data type | Name | Description | |
|---|--|---|--|
| $\mathtt{dip}_{\scriptscriptstyle{-}}\mathtt{ImageArray}$ | in | An array of input images | |
| dip_ImageArray | out | An array of output images | |
| dip_ImageArray * | newOut | Returns an array containing the replacement output | |
| | | images | |
| dip_BooleanArray | saved An array of booleans indicating which input images | | |
| | | are safely stored | |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew. May | |
| | | not be zero | |

SEE ALSO

 ${\tt ImageGetData}$

ImageStrip

Restore an image to its initial ("raw") state

SYNOPSIS

dip_Error dip_ImageStrip(image)

FUNCTION

Free any pixel data associated with the image and return all fields to their initial ("raw") state. Essentially the image is returned to the state it was in right after it was allocated with ImageNew.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-------|--------------------------|
| ${\tt dip_Image}$ | image | The image to be stripped |

SEE ALSO

The image structure

ImageNew, ImageForge, ImageFree, ImageCopyProperties

ImageWrite

Write grey-value image to file (in dipIO)

SYNOPSIS

dip_Error dipio_ImageWrite (image, filename, physDims, format, compression)

FUNCTION

This function writes a grey-vlaue image to a file, overwriting any other file with the same name. physDims gives physical dimensions of the image, and can be set to 0 for default values. Not all file formats are able to store physical dimensions. Get the format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats. If format is 0, ICSv2 is used.

ARGUMENTS

| Data type | Name | Description | |
|------------------------|-------------|-------------------------------------|--|
| dip_Image | image | Output image | |
| dip_String | filename | File name | |
| dip_PhysicalDimensions | physDims | Physical dimensions structure. See | |
| | | PhysicalDimensionsNew | |
| dip_int | format | ID of file format | |
| dipio_Compression | compression | Compression method and level. See | |
| | | Compression methods for image files | |

SEE ALSO

ImageWriteColour, ImageWriteCSV, ImageWriteEPS, ImageWriteFLD, ImageWriteGIF, ImageWriteICS, ImageWritePS, ImageWriteTIFF, ImageWriteJPEG, ImageRead

ImageWriteColour

Write colour image to file (in dipIO)

SYNOPSIS

dip_Error dipio_ImageWriteColour (image, filename, photometric, physDims, format, compression)

FUNCTION

This function writes a colour image to a file, overwriting any other file with the same name. photometric must be set to the correct value. Not all file formats support all photometric values, and some don't support colour at all. physDims gives physical dimensions of the image, and can be set to 0 for default values. Not all file formats are able to store physical dimensions. Get the format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats. If format is 0, ICSv2 is used.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|--------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |
| | | (==colour space) |
| dip_PhysicalDimensions | physDims | Physical dimensions structure. |
| | | See PhysicalDimensionsNew |
| dip_int | format | ID of file format |
| dipio_Compression | compression | Compression method and level. |
| | | See Compression methods for |
| | | image files |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|---|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, |
| | yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* |
| | and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* |
| | and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and |
| | value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and |
| | value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as |
| | DIPIO_PHM_CMYK |

Most file formats support only some of these.

ImageWriteCSV

Write image to a comma-separated-value file (in dipIO)

SYNOPSIS

```
#include "dipio_csv.h"
dip_Error dipio_ImageWriteCSV ( image, filename, separator )
dip_Error dipio_ImageWriteCSV ( dip_Image, dip_String, char );
```

FUNCTION

This function writes the image to a comma-separated-values file, overwriting any other file with the same name. Optionally, an other separator than the comma can be specified using separator. Sometimes a space, a tab or a colon are used instead. Each line of image data is ended by a newline.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | image | Output image |
| dip_String | filename | File name |
| char | separator | Optional alternative separator character |

SEE ALSO

ImageWrite, ImageReadCSV

ImageWriteEPS

Write image to Encapsulated PostScript file (in dipIO)

SYNOPSIS

```
#include "dipio_ps.h"
dip_Error dipio_ImageWriteEPS ( image, filename, photometric, xcm, ycm, border )
```

FUNCTION

This function writes the image to an Encapsulated PostScript file, overwriting any other file with the same name. Set the image size in xcm and ycm. border sets the size of the border around the image. If border is 0, no border is drawn. For colour images, set photometric (supported are RGB and CMYK) and write the colour channels along the third image dimension.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|---------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |
| dip_float | xcm | X-size of image in cm. |
| dip_float | ycm | Y-size of image in cm. |
| dip_int | border | Thickness of border, zero is no |
| | | border |

The enumerator ${\tt dipio_PhotometricInterpretation}$ contains the following constants:

399

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as DIPIO_PHM_CMYK |

Most file formats support only some of these.

ImageWriteGIF

Write image to a GIF file (in dipIO)

SYNOPSIS

```
#include "dipio_gif.h"
dip_Error dipio_ImageWriteGIF ( image, filename, labelImage )
```

FUNCTION

This function writes the gray-value image to a GIF file, overwriting any other file with the same name. Optionally, an integer-typed image can be identified as a labeled image using labelImage. In that case a colour GIF image will be saved.

ARGUMENTS

| Data type | Name | Description |
|-------------|------------|--|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dip_Boolean | labelImage | Regard an integer image as a labeled image |

SOFTWARE

This function uses GifLib (version 4.1.0 or later), which supports GIF 87a & 98a. Copyright (c)1997 Eric S. Raymond

SEE ALSO

ImageWrite, ImageReadGIF, ImageIsGIF

ImageWriteICS

Write ICS image to file (in dipIO)

SYNOPSIS

```
#include "dipio_ics.h"
dip_Error dipio_ImageWriteICS ( image, filename, photometric, physDims, history, sigbits, version, compression )
```

FUNCTION

This function writes the image to an ICS file, overwriting any other file with the same name. version can set to 1 to use the ICS v.1.0 file format (the 2-file version), instead of ICS v.2.0. For colour images, set photometric and write the colour channels along the last image dimension. Set sigbits only if the number of significant bits is different from the full range of the data type of image (use 0 otherwise). physDims can be set to 0 to fill out default values. history can be 0 if you do not want to bother.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|--------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |
| dip_PhysicalDimensions | physDims | Physical dimensions structure. |
| | | See PhysicalDimensionsNew |
| dip_StringArray | history | Tags that are written to the |
| | | history in the ICS header |
| dip_int | sigbits | Number of significant bits. |
| dip_int | version | ICS version |
| dipio_Compression | compression | Compression method and level. |
| | | See Compression methods for |
| | | image files |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|---|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |
| DIPIO_PHM_CMYK | CMYK image (the first four planes are cyan, magenta, |
| | yellow and black) |
| DIPIO_PHM_CIELUV | CIE L*u'v' image (the first three planes are luminosity, u* |
| | and v*) |
| DIPIO_PHM_CIELAB | CIE L*a*b* image (the first three planes are luminosity, a* |
| | and b*) |
| DIPIO_PHM_CIEXYZ | CIE XYZ (the first three planes are X, Y and Z) |
| DIPIO_PHM_CIEYXY | CIE Yxy (the first three planes are Y, x and y) |
| DIPIO_PHM_HCV | HCV image (the first three planes are hue, chroma and |
| | value) |
| DIPIO_PHM_HSV | HSV image (the first three planes are hue, saturation and |
| | value) |
| DIPIO_PHM_DEFAULT | Same as DIPIO_PHM_GREYVALUE |
| DIPIO_PHM_GENERIC | Anything can be coded in the channels; the same as |
| | DIPIO_PHM_CMYK |

Most file formats support only some of these.

ImageWriteJPEG

Write JPEG image to file (in dipIO)

SYNOPSIS

```
#include "dipio_jpeg.h"
dip_Error ImageWriteJPEG ( image, filename, photometric, physDims, complevel
)
```

FUNCTION

This function writes the image to a JPEG file, overwriting any other file with the same name. photometric can set to let the function know how to write the JPEG image (supported colour space is RGB).

If photometric is not DIPIO_PHM_GRAYVALUE, a 3D image is expected, in which the different planes are stored along the 3rd dimension.

physDims gives physical dimensions of the image, which will be used to set the dots per inch property of the JPEG file. It can be set to 0 for default values (300 dpi). If the physDims->dimensionUnits is not given, meters are assumed.

complevel is a number between 1 (worst quality, smallest files) and 100 (best quality, largest files). Setting complevel to 0 uses the default compression level, which is 90.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|--------------------------------|
| $	ext{dip}_{-}	ext{Image}$ | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |
| dip_PhysicalDimensions | physDims | Physical dimensions structure. |
| | | See PhysicalDimensionsNew |
| dipio_uint | complevel | Compression level |

The enumerator dipio_PhotometricInterpretation contains the following constants:

405

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |
| DIPIO_PHM_RGB | RGB image (the first three planes are red, green and blue) |
| DIPIO_PHM_RGB_NONLINEAR | Non-linear R'G'B' image (RGB channels to the power of 0.4) |
| DIPIO_PHM_CMY | CMY image (the first three planes are cyan, magenta and yellow) |

ImageWritePS

Write image to PostScript file (in dipIO)

SYNOPSIS

```
#include "dipio_ps.h"
dip_Error dipio_ImageWritePS ( image, filename, photometric, caption, xcm,
ycm, border )
```

FUNCTION

This function writes the image to a PostScript file, overwriting any other file with the same name. Set the image size in xcm and ycm. border sets the size of the border around the image. If border is 0, no border is drawn. You can give the page a title through caption. For colour images, set photometric (supported are RGB and CMYK) and write the colour channels along the third image dimension.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|---------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |
| dip_String | caption | Title for page |
| dip_float | xcm | X-size of image on page, in cm. |
| dip_float | ycm | Y-size of image on page, in cm. |
| dip_int | border | Thickness of border, zero is no |
| | | border |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|--|

ImageWriteTIFF

Write TIFF image to file (in dipIO)

SYNOPSIS

```
#include "dipio_tiff.h"
dip_Error ImageWriteTIFF ( image, filename, photometric, physDims, compression )
```

FUNCTION

This function writes the image to a TIFF file, overwriting any other file with the same name. photometric can set to let the function know how to write the TIFF image (supported colour spaces are RGB, CIE Lab and CMYK).

If photometric is not DIPIO_PHM_GRAYVALUE, a 3D image is expected, in which the different planes are stored along the 3rd dimension.

physDims gives physical dimensions of the image, which will be used to set the dots per inch property of the TIFF file. It can be set to 0 for default values (300 dpi). If the physDims->dimensionUnits is not given, meters are assumed.

ARGUMENTS

| Data type | Name | Description |
|---------------------------------|-------------|--------------------------------|
| dip_Image | image | Output image |
| dip_String | filename | File name |
| dipio_PhotometricInterpretation | photometric | Photometric interpretation |
| dip_PhysicalDimensions | physDims | Physical dimensions structure. |
| | | See PhysicalDimensionsNew |
| dipio_Compression | compression | Compression method and level. |
| | | See Compression methods for |
| | | image files |

The enumerator dipio_PhotometricInterpretation contains the following constants:

| Name | Description |
|-------------------------|--|
| DIPIO_PHM_GREYVALUE | No colour information present; it's a grey-value image. |

IncoherentOTF

Generates an incoherent OTF

SYNOPSIS

```
#include "dip_microscopy.h"
dip_Error dip_IncoherentOTF ( out, defocus, xNyquist, amplitude, otf )
```

DATA TYPES

Output: sfloat

FUNCTION

This function implements the formulae for a (defocused) incoherent OTF as described by Castleman. When defocus is unequal to zero, either the Stokseth approximation or the Hopkins approximation is used. The defocus is defined a the maximum defocus path length error divided by the wave length (See Castleman for details). The summation over the Bessel functions in the Hopkins formluation, is stopped when the change is smaller than DIP_MICROSCOPY_HOPKINS_OTF_CUTOFF.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|-------------------|
| dip_Image | out | Output |
| dip_float | defocus | Defocus |
| dip_float | xNyquist | Oversampling |
| dip_float | amplitude | Amplitude |
| dipf_IncoherentOTF | otf | Otf approximation |

The dipf_IncoherentOTF enumeration supports the following flags:

| Name | Description |
|-----------------------------|----------------------------|
| DIP_MICROSCOPY_OTF_STOKSETH | Stokseth OTF approximation |
| DIP_MICROSCOPY_OTF_HOPKINS | Hopkins OTF approximation |

IndexToCoordinate

Convert pixel index to coordinate

SYNOPSIS

```
#include "dip_coordsindx.h"
dip_Error dip_IndexToCoordinate ( index, coordinate, stride )
```

FUNCTION

This function is identical to IndexToCoordinateWithSingletons, but does not handle images with singleton dimensions (dimensions where the size is 1). Please use the other function instead, this one is provided for backwards compatability only.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|------------|--------------------|
| $\mathtt{dip}_{-}\mathtt{int}$ | index | lineair index |
| dip_IntegerArray | coordinate | output coordinates |
| dip_IntegerArray | stride | stride array |

SEE ALSO

 ${\tt IndexToCoordinateWithSingletons, CoordinateToIndex}$

IndexToCoordinateWithSingletons

Convert pixel index to coordinate

SYNOPSIS

```
#include "dip_coordsindx.h"
dip_Error dip_IndexToCoordinateWithSingletons ( index, coordinate, size,
stride )
```

FUNCTION

This function converts an pixel index of an image to a coordinate array. The conversion is done by calculating the modulus of the index with the stride and size arrays obtained from the image. coordinate has to be an allocated integer array with its size equal to the size of stride and size.

A set of macros can be used instead of this function to avoid some overhead when repeatedly converting linear indices to coordinates for the same image:

DIPXJ(dip_IntegerArrayNew(&coordinates, stride->size, 0, rg));

/* Now, every time you need to obtain the coordinates for an index, do: */

```
DIP_FNR_DECLARE;  /* Declares dip_Registry rg */
dip_Image image;
dip_int index;
dip_IntegerArray coordinates;

dip_IntegerArray size;
dip_IntegerArray stride;

DIP_INDEX_TO_COORDINATE_DECL( ix );  /* This macro declares variable "ix", name it whatever
DIP_FNR_INITIALISE;

/* ... */

DIPXJ( dip_ImageGetDimensions( image, &size, rg ));
DIPXJ( dip_ImageGetStride( image, &stride, rg ));
DIP_INDEX_TO_COORDINATE_INIT( size, stride, ix, rg );  /* This macro initialises variable '
```

DIP_INDEX_TO_COORDINATE(index, coordinates, stride, ix);

ARGUMENTS

| Data type | Name | Description |
|---|------------|--------------------|
| $\mathtt{dip}_{-}\mathtt{int}$ | index | lineair index |
| $\mathtt{dip}_{	extsf{-}}\mathtt{IntegerArray}$ | coordinate | output coordinates |
| $\mathtt{dip}_{\scriptscriptstyle{-}}\mathtt{IntegerArray}$ | size | image size array |
| dip_IntegerArray | stride | stride array |

IntegerArrayFind

Find value in array

SYNOPSIS

dip_Error dip_IntegerArrayFind (array, value, index, found)

FUNCTION

Finds a value in an array and "returns" its index in the array. If found is zero, IntegerArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP_FALSE if value is not found).

ARGUMENTS

| Data type | Name | Description |
|---|-------|--------------------------|
| $\mathtt{dip}_{	extsf{-}}\mathtt{IntegerArray}$ | array | Array to find value in |
| dip_int | value | Value to find |
| dip_int * | index | Index of the found value |
| dip_Boolean * | found | Value found or not |

IsScalar

Determines whether an image is a scalar

SYNOPSIS

dip_Error dip_IsScalar(image, answer)

FUNCTION

Determines whether an image is of the DIP_IMTP_SCALAR type. If answer is not zero, the verdict is passed in this variable. Otherwise, dip_IsScalar returns an error in case image fails to be a scalar.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------|-------------------------------|
| ${\tt dip_Image}$ | image | The image under investigation |
| dip_Boolean * | answer | The verdict |

Kuwahara

Edge perserving smoothing filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_Kuwahara ( in, out, se, boundary, param, shape )
```

DATA TYPES

binary, integer, float

FUNCTION

This function implements the kuwahara edge-preserving smoothing function. See section 9.4, "Smoothing operations", in Fundamentals of Image Processing for a description of the algorithm. However, this function does not implement the classical kuwahara filter, which only compares the variance of four regions in the filter window. Instead, it compares the variance of every region specified by the filter shape and size centered within the filter window.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|-------------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_Image | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

SEE ALSO

KuwaharaImproved

Edge perserving smoothing filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_KuwaharaImproved ( in, out, se, boundary, param, shape,
threshold )
```

DATA TYPES

binary, integer, float

FUNCTION

This function implements an improved version of Kuwahara, see that function's description for more information. This function adds a threshold parameter that avoids false edges in uniform regions. If the difference between maximal and minimal variance within the filter window is smaller or equal to threshold, the centre pixel is taken, instead of the minimum. Setting threshold to zero yields the same result as Kuwahara.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-----------|---|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_Image | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |
| dip_float | threshold | Minimal variance difference within window |

431

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

Label

Label a binary image

SYNOPSIS

```
#include "dip_regions.h"
dip_Error dip_Label ( in, out, connectivity, flags, minsize, maxsize, nol, boundary )
```

DATA TYPES

binary

FUNCTION

The output is an integer image. Each object (respecting the connectivity, see The connectivity parameter) in the input image receives a unique number. This number ranges from 1 to the number of objects in the image. The pixels in the output image corresponding to a given object are set to this number (label). The remaining pixels in the output image are set to 0. The minsize and maxsize set limits on the size of the objects, if the flag DIP_LB_THRESHOLD_ON_SIZE is set: Objects smaller than minsize or larger than maxsize do not receive a label and the corresponding pixels in the output image are set to zero. Setting minsize to zero implies that there is no check with respect to the minimum size of the object, and the same holds for maxsize and the maximum size of the object. If the flag DIP_LB_LABEL_IS_SIZE is set, the objects' labels are set to the objects' sizes. The boundary conditions are generally ignored (labeling stops at the boundary). The exception is DIP_BC_PERIODIC, which is the only one that makes sense for this algorithm.

ARGUMENTS

| Data type | Name | Description |
|-------------------|--------------|---|
| dip_Image | in | Input binary image |
| dip_Image | out | Output label image |
| dip_int | connectivity | Connectivity |
| dip_int | flags | 0, or a logical OR of the flags described above |
| dip_int | minsize | Minimum size of the objects (0=do not check) |
| dip_int | maxsize | Maximum size of the objects (0=do not check) |
| dip_int * | nol | Pointer to dip_int. Used for returning the number |
| | | of objects. May be set to 0. |
| dip_BoundaryArray | boundary | Boundary conditions |

Laplace

Second order derivative filter

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_Laplace ( in, out, boundary, ps, sigmas, tc, flavour )
```

DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float**

FUNCTION

Computes the Laplace of an image using the Derivative function.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|----------|-----------------------------|
| $dip_{-}Image$ | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | ps | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_float | tc | Truncation of Gaussian, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative flavour |

The enumerator flavour parameter is one of:

| Name | Description |
|-------------------|--|
| DIP_DF_DEFAULT | Default derivative flavour (==DIP_DF_FIRGAUSS) |
| DIP_DF_FIRGAUSS | Gaussian family, FIR implementation, Gauss |
| DIP_DF_IIRGAUSS | Gaussian family, IIR implementation, GaussIIR |
| DIP_DF_FTGAUSS | Gaussian family, FT implementation, GaussFT |
| DIP_DF_FINITEDIFF | Finite difference implementation, FiniteDifferenceEx |

SEE ALSO

See section 9.5, "Derivative-based operations", in Fundamentals of Image Processing.

 ${\tt Derivative, GradientMagnitude, GradientDirection2D, Dgg, LaplacePlusDgg, LaplaceMinDgg}$

LaplaceMinDgg

Second order derivative filter

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_LaplaceMinDgg ( in, out, boundary, ps, sigmas, tc, flavour )
```

DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float**

FUNCTION

Computes Laplace - Dgg. For two-dimensional images this is equivalent to the second order derivative in the direction perpendicular to the gradient direction.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|----------|-----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | ps | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_float | tc | Truncation of Gaussian, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative flavour |

The enumerator flavour parameter is one of:

| Name | Description |
|-------------------|--|
| DIP_DF_DEFAULT | Default derivative flavour (==DIP_DF_FIRGAUSS) |
| DIP_DF_FIRGAUSS | Gaussian family, FIR implementation, Gauss |
| DIP_DF_IIRGAUSS | Gaussian family, IIR implementation, GaussIIR |
| DIP_DF_FTGAUSS | Gaussian family, FT implementation, GaussFT |
| DIP_DF_FINITEDIFF | Finite difference implementation, FiniteDifferenceEx |

 ${\tt Derivative,\,GradientMagnitude,\,GradientDirection2D,\,Laplace,\,Dgg,\,LaplacePlusDgg}$

LaplacePlusDgg

Second order derivative filter

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_LaplacePlusDgg ( in, out, boundary, ps, sigmas, tc, flavour )
```

DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float**

FUNCTION

Computes the laplace and the second derivative in gradient direction of an image using the Derivative function and adds the results. The zero-crossings of the result correspond to the edges in the image, just as for the individual Laplace and Dgg operators. The localization is improved by an order of magnitude with respect to the individual operators.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|----------|-----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | ps | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_float | tc | Truncation of Gaussian, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative flavour |

The enumerator flavour parameter is one of:

| Name | Description |
|-------------------|--|
| DIP_DF_DEFAULT | Default derivative flavour (==DIP_DF_FIRGAUSS) |
| DIP_DF_FIRGAUSS | Gaussian family, FIR implementation, Gauss |
| DIP_DF_IIRGAUSS | Gaussian family, IIR implementation, GaussIIR |
| DIP_DF_FTGAUSS | Gaussian family, FT implementation, GaussFT |
| DIP_DF_FINITEDIFF | Finite difference implementation, FiniteDifferenceEx |

Lee

Morphological edge detector

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Lee ( in, out, se, boundary, param, shape, edgeType, flags )
```

DATA TYPES

integer, float

FUNCTION

Implements a morphological edge detector based on the minimum of two complementary morphological operations. These can be chosen through the edgeType parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |
| dip_MphEdgeType | edgeType | Edge type |
| dipf_LeeSign | flags | Lee sign flag |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

The enumerator ${\tt dip_MphEdgeType}$ contains the following constants:

| Name | Description |
|-----------------|---|
| DIP_MPH_TEXTURE | Response is limited to edges in texture |
| DIP_MPH_OBJECT | Response is limited to object edges |
| DIP_MPH_BOTH | All edges produce equal response |

The enumerator dipf_LeeSign contains the following constants:

| Name | Description |
|------------------|------------------------|
| DIP_LEE_UNSIGNED | Absolute edge strength |
| DIP_LEE_SIGNED | Signed edge strength |

SEE ALSO

MorphologicalGradientMagnitude, MorphologicalRange, MultiScaleMorphologicalGradient, Tophat

Lesser

Compare grey values in two images

SYNOPSIS

dip_Error dip_Lesser (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function sets each pixel in out to "true" when for corresponding pixels in1 < in2. This is the same as Compare with the DIP_SELECT_LESSER selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| ${\tt dip_Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| dip_Image | out | Output |

SEE ALSO

Compare, Threshold, Equal, Greater, NotEqual, NotGreater, NotLesser, SelectValue, NotZero

Ln

arithmetic function

SYNOPSIS

dip_Error dip_Ln (in, out)

DATA TYPES

binary, integer, **float**

FUNCTION

Computes the natural logarithm of the input image values.

ARGUMENTS

| Data type | Name | Description | |
|--------------------|------|-------------|--|
| ${\tt dip_Image}$ | in | Input | |
| dip_Image | out | Output | |

SEE ALSO

Sqrt, Exp, Exp2, Exp10, Log2, Log10

LnGamma

mathematical function

SYNOPSIS

dip_Error dip_LnGamma (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the natural logarithm of the gamma function of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| ${\tt dip_Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

LnNormError

difference measure

SYNOPSIS

dip_Error dip_LnNormError (in1, in2, mask, out, order)

DATA TYPES

binary, integer, float, complex

FUNCTION

Calculates the order norm difference between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

ARGUMENTS

| Data type | Name | Description | | |
|---|-------|--------------|--|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input | | |
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in2 | Second input | | |
| dip_Image | mask | Mask | | |
| dip_Image | out | Output | | |
| dip_float | order | Order | | |

SEE ALSO

 ${\tt MeanError}, \, {\tt MeanSquareError}, \, {\tt RootMeanSquareError}, \, {\tt MeanAbsoluteError}, \, {\tt IDivergence}$

LocalMinima

Marks local minima (or regional minima)

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_LocalMinima ( in, mask, out, connectivity, max_depth, max_size, binaryOutput )
```

DATA TYPES

integer, float

FUNCTION

The binary output image is true on all pixels belonging to the minima of a region (as defined by the watershed). To find local maxima, use the inverse of the image as input to this function (see Invert). If binaryOutput is DIP_FALSE, the output is a labelled image instead of a binary one. In this case, pixels belonging to the same local minimum are assigned the same value.

The algorithm is based on the watershed transform, see Watershed for information on the parameters.

Minima is a different algorithm to obtain local minima; Maxima yields the local maxima.

ARGUMENTS

| Data type | Name | Description |
|---|--------------|--|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | mask | Mask |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output (binary) |
| $\mathtt{dip}_{-}\mathtt{int}$ | connectivity | Connectivity |
| dip_float | max_depth | Maximum depth of a region that can be merged |
| dip_int | max_size | Maximum size of a region that can be merged |
| dip_Boolean | binaryOutput | DIP_FALSE if the output should be a labelled image |

SEE ALSO

Watershed, SeededWatershed, UpperEnvelope, Minima, Maxima

Log10

arithmetic function

SYNOPSIS

dip_Error dip_Log10 (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the base ten logarithm of the input image values.

ARGUMENTS

| Data type | Name | Description | |
|--------------------|------|-------------|--|
| ${\tt dip_Image}$ | in | Input | |
| dip_Image | out | Output | |

SEE ALSO

Sqrt, Exp, Exp2, Exp10, Ln, Log2

Log2

arithmetic function

SYNOPSIS

dip_Error dip_Log2 (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the base two logarithm of the input image values.

ARGUMENTS

| Data type | Name | Description | |
|--------------------|------|-------------|--|
| ${\tt dip_Image}$ | in | Input | |
| dip_Image | out | Output | |

SEE ALSO

Sqrt, Exp, Exp2, Exp10, Ln, Log10

macros.h

Various macros

DESCRIPTION

The include files dip_macros.h contains a number of useful macros.

Math macros

| DIP_ABS(x) | Absolute value of x |
|------------------------------|--|
| DIP_MAX(x, y) | Maximum of x and y |
| DIP_MIN(x, y) | Minimum of x and y |
| DIP_FUNC(funcName, suffix) | Attaches the suffix to the function name, |
| | and puts and underscore in between. |
| DIP_SWAP(x, y, z) | Swaps variables x and y, using temporary |
| | variable z . Must be followed by a trailing |
| | α. α ; |

Macros for handling complex numbers:

| DIP_REAL(x) | Real part of complex number x |
|-------------------------|---|
| DIP_IMAGINARY(x) | Imaginary part of complex number x |
| DIP_SQUARE_MODULUS(x) | Square modulus of complex number x |
| DIP_MODULUS(x) | Modulus of complex number x |
| DIP_PHASE(x) | Phase of complex number x |

Binary I/O macros

| DIP_BINARY_MASK(mask, plane) | Computes a binary mask from the plane |
|------------------------------------|---------------------------------------|
| | value |
| DIP_BINARY_READ(in, mask) | Returns the binary value from in |
| DIP_BINARY_WRITE(out, val, mask) | Writes the value of val to out |

Random access I/O macros:

```
DIP_PIXEL_GET( ip, pos, stride, value )
DIP_PIXEL_SET( ip, pos, stride, value )
```

get/set the value of the pixel at position pos from data pointer ip with strides stride. Both pos and stride are dip_IntegerArrays.

```
DIP_PIXEL_ADD( ip, pos, stride, value )
DIP_PIXEL_SUB( ip, pos, stride, value )
DIP_PIXEL_MUL( ip, pos, stride, value )
DIP_PIXEL_DIV( ip, pos, stride, value )
```

add/subtract/multlipy/divide the value with the pixel-value at position pos from data pointer ip with strides stride. Both pos and stride are dip_IntegerArrays.

Map

Remaps an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Map ( in, out, map, mirror )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function maps the dimensions of the output image to (different) dimensions of the input image. The array index of map specifies the dimension of the output image, the value of the array element of map specifies to which dimension in the input image it corresponds. Optionally, the dimensions can be mirrored, when the value of the corresponding array element in mirror is set to DIP_TRUE. The mirror operation is performed after the mapping operation.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------|--------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| $dip_{-}Image$ | out | Output image |
| dip_IntegerArray | map | Map array |
| dip_BooleanArray | mirror | Mirror array |

SEE ALSO

Mirror

Max

arithmetic function

SYNOPSIS

dip_Error dip_Max (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function computes out = max (in1, in2) on a pixel by pixel basis. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description | |
|----------------------------------|------|--------------|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input | |
| $dip_{-}Image$ | in2 | Second input | |
| dip_Image | out | Output | |

SEE ALSO

MaxFloat, Min, MinFloat

MaxFloat

arithmetic function

SYNOPSIS

dip_Error dip_MaxFloat (in, out, constant)

DATA TYPES

binary, integer, float

FUNCTION

This function computes out = max(in, constant) on a pixel by pixel basis. The data types of the in1 image and constant may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_float | constant | Constant |

SEE ALSO

Max, Min, MinFloat

Maxima

Detects local maxima

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_Maxima ( in, mask, out, connectivity, booleanOutput )
```

DATA TYPES

integer, float

FUNCTION

This function detects local maxima.

The algorithm finds a connected set of pixels with identical value, an no neighbours with higher value. This set is a local maximum and its pixels are set to 1 in the output image. If booleanOutput is false, the output image is a labelled image.

For images that have large plateaus (regions of constant value) that are not local maxima, this function can be quite slow. For example, an image that is zero everywhere except for a small peak somewhere. For such an image it is recommended to use the mask input, for example with the output of a threshold operation.

ARGUMENTS

| Data type | Name | Description |
|-------------|---------------|-----------------------------|
| dip_Image | in | Input image |
| dip_Image | mask | Mask image |
| dip_Image | out | Binary output image |
| dip_int | connectivity | Connectivity |
| dip_Boolean | booleanOutput | Give a binary output image? |

NOTE

If you are looking for the old version of Maxima, it is still available through the following combination of commands:

```
dip_Dilation( in, out, se, boundary, param, shape );
dip_Equal( in, out, out );
```

| | | _ | Λ. | | \sim |
|---|----|---|----|-----|--------|
| S | ⊢. | _ | Δ | l S | . () |
| | | | | | |

 ${\tt Minima, Subpixel Maxima, Local Minima, Seeded Watershed, Grow Regions}$

Maximum

statistics function

SYNOPSIS

dip_Error dip_Maximum (in, mask, out, ps)

DATA TYPES

binary, integer, float

FUNCTION

Calculates the maximum of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask |

Measure

Measure object features

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_Measure ( measurement, featureID, featureParams, objectID,
objectIm, intensityIm, connectivity, physDims )
```

DATA TYPES

objectIm: integer

intensityIm: integer, float

FUNCTION

The Measure function is the top-level function of DIPlib's measurement library. This function performs measurements of the objects in the specified objectIm image. The measurements to be performed are specified by the featureID array of measurement function IDs. If featureParams is non-zero, its size should equal that of featureID. Although the current implementation of Measure does not make use of this argument, future versions will pass the data pointers of the featureParams to the corresponding measurement functions. featureParams should be set to zero for now.

The list of object IDs on which the measurements have to be performed is specified by objectID. If it is zero, Measure will call GetObjectLabels to obtain a list of all non-zero values in objectIm. The objectID values should be unequal to zero.

The state of measurement should be raw (see MeasurementNew), since Measure will forge the measurement data structure by calling MeasurementForge.

The intensityIm image defines the pixel intensity of the objects, whose shape is defined by objectIm. If none of the measurements specified in featureID require the grey-value image, it can be set to NULL.

The physDims parameter defines the physical dimensions of the pixel sizes and pixel intensity. See PhysicalDimensionsNew for more information.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------|-------------------|-----------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_IntegerArray | featureID | Array of measurement function IDs |
| $	ext{dipVoidPointerArray}$ | featureParams (0) | Set to zero |
| dip_IntegerArray | objectID (0) | Array of Object IDs |
| dip_Image | objectIm | Image containing object IDs, i.e. |
| | | object labels |
| ${\tt dip_Image}$ | intensityIm | Intensity image |
| dip_int | connectivity | Connectivity of object's contour |
| | | pixels, see The connectivity |
| | | parameter |
| dip_PhysicalDimensions | physDims | Structure specifying the physical |
| | | dimensions of the image pixels |

MeasurementFeatureConvert

Convert the data of a measurement feature

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureConvert ( in, featureID, inID, out, outID,
resources )
```

FUNCTION

This function convert the data of object inID in measurement in measured by feature featureID to object outID in out.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-----------|--|
| dip_Measurement | in | Input measurement data structure |
| dip_int | featureID | ID of the measurement feature |
| dip_int | inID | ID of the object in in |
| dip_Measurement | out | Output measurement data structure |
| dip_int | outID | ID of the object in out |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

Measure, MeasurementNew

MeasurementFeatureDescription

Measurement Description access function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureDescription ( measurement, featureID,
description, resources )
```

FUNCTION

The MeasurementObjectData, MeasurementObjectValue and MeasurementFeatureDescription functions provide access to the functions that are registered by each measurement function. See also MeasurementFeatureRegister.

This function gives access to a structure containing the name, a short description of the measurement feature, as well as the labels and units of the data measured by the feature specified with featureID. Use the functions FeatureDescriptionGetName, FeatureDescriptionGetDescription, FeatureDescriptionGetLabels and FeatureDescriptionGetUnits to access the values in the description structure.

ARGUMENTS

| Data type | Name | Description |
|--------------------------|-------------|---|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement feature ID |
| dip_FeatureDescription * | description | Pointer to a dip_FeatureDescription |
| | | structure containing a description of the |
| | | specified feature |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

MeasurementFeatureFormat

Feature data format convenience function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureFormat ( measurement, featureID, format )
```

FUNCTION

This function is a convenience function on top of MeasurementObjectValue, providing an easy access to the data format of the measurement values of the featureID measurement function.

ARGUMENTS

| Data type | Name | Description |
|-------------------------------|-------------|-----------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| dipf_MeasurementValueFormat * | format | Pointer to measurement value data |
| | | format |

SEE ALSO

MeasurementObjectValue, MeasurementNew

DIP*lib* function reference 473

MeasurementFeatureRegister

Register a measurement function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegister ( registry )
```

FUNCTION

This function registers a measurement function, specified by registry. Once a function is registered, it can be used through the Measure function by specifying registry.id.rtid as the measurement ID. registry contains pointers to a series of functions related to making the measurement, and contains information on how these functions should be called. See below for more information.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|----------|-------------|
| dip_MeasurementFeatureRegistry | registry | Registry |

THE REGISTRY STRUCTURE

The dip_MeasurementFeatureRegistry structure contains the following fields:

| Data type | Name | Description |
|--------------------------------|-----------------|------------------------------|
| dip_Identifier | id | Unique identifier |
| dipf_FeatureMeasureFunction | type | Type of function measure |
| | | points to |
| dip_FeatureCreateFunction | create | Function pointer, see |
| | | FeatureCreateFunction |
| dip_FeatureComposeFunction | compose | Function pointer, see |
| | | FeatureComposeFunction |
| dip_FeatureMeasureFunction | measure | Union of function pointers |
| dip_FeatureValueFunction | value | Function pointer, see |
| | | FeatureValueFunction |
| dip_FeatureDescriptionFunction | description | Function pointer, see |
| | | FeatureDescriptionFunction |
| dip_FeatureConvertFunction | convert | Function pointer, see |
| | | FeatureConvertFunction |
| dip_int | iterations | Currently ignored (set to 1) |
| dip_Boolean | needIntensityIm | Whether or not a grey-value |
| | | image is needed |

dip_Identifier is a struct with two values: uuid and rtid. rtid is of type dip_int, and needs to be set to a unique number (use GetUniqueNumber for that). uuid is curently ignored, but should be set to a universally unique number by using the time, date and processor ID at the time of writing the code. The UNIX command uuidgen should be used for this.

measure points to the main measuring function, and can be of four different types, based on how it does the measuring. measure is a union with the following fields:

| Data type | Name | Description |
|------------------------------|-----------|---------------------------------------|
| dip_FeatureLineFunction | line | Takes one image line at the time, see |
| | | FeatureLineFunction |
| dip_FeatureImageFunction | image | Takes the whole image at once, see |
| | | FeatureImageFunction |
| dip_FeatureChainCodeFunction | chaincode | Takes one chain code at the time, see |
| | | FeatureChainCodeFunction |
| dip_FeatureCompositeFunction | composite | Combines the results of various other |
| | | measurements, see |
| | | FeatureCompositeFunction |

The type flag should match the function type pointed to, and can be one of the following:

| Name | Description |
|----------------------------------|--------------------------|
| DIP_MSR_FUNCTION_LINE_BASED | measure.line is set |
| DIP_MSR_FUNCTION_IMAGE_BASED | measure.image is set |
| DIP_MSR_FUNCTION_CHAINCODE_BASED | measure.chaincode is set |
| DIP_MSR_FUNCTION_COMPOSITE | measure.composite is set |

create points to a function that initialises any data before the measurement can start.
value points to a function that returns the measurement result (called by
MeasurementObjectValue). description points to a function that returns information on

the measurement performed (called by MeasurementFeatureDescription). convert points to a function that copies the collected measurement data to a second measurement object (called MeasurementFeatureConvert). Finally, the compose element points to a function that returns the list of measurement IDs that the DIP_MSR_FUNCTION_COMPOSITE function depends on. This value is ignored for other types of measurement functions.

needIntensityIm should be set if the measurement function expects a grey-value input as well as the labeled image.

MeasurementFeatureRegistryFeatureDescription

Get the feature description of a registered measurement feature

SYNOPSIS

#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegistryFeatureDescription (featureID,
description, resources)

FUNCTION

This function obtains the feature description information of the measurement feature specified by featureID.

ARGUMENTS

| Data type | Name | Description |
|--------------------------|-------------|---|
| dip_int | featureID | Measurement feature ID |
| dip_FeatureDescription * | description | pointer to a dip_FeatureDescription |
| | | structure containing descriptive |
| | | information of the measurement feature. |
| | | This data can be accessed with |

${\tt MeasurementFeatureRegistryFeatureNeedsIntensityImage}$

Checks whether the measurement function needs an intensity image

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegistryFeatureNeedsIntensityImage (
featureID, veredict )
```

FUNCTION

This function sets veredict to DIP_TRUE if the measurement feature specified by featureID requires a grey-value image, or DIP_FALSE otherwise.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|------------------------|
| dip_int | featureID | Measurement feature ID |
| dip_Boolean * | veredict | Return value |

SEE ALSO

MeasurementFeatureSize

Feature data convenience function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureSize ( measurement, featureID, size )
```

FUNCTION

This function is a convenience function on top of MeasurementObjectValue, providing an easy access to the number of the measurement values of the featureID measurement function.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|-------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | ID of the measurement feature |
| dip_int * | size | Number of measurement values |

SEE ALSO

MeasurementObjectValue, MeasurementNew

MeasurementFeatureValid

Verify a measurement feature ID

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureValid ( measurement, featureID, verdict )
```

FUNCTION

This function determines whether featureID is a valid measurement feature, by verifying whether featureID equals the ID of one of the registered measurement features. If verdict is not zero, the result (DIP_TRUE or DIP_FALSE) is stored in verdict, otherwise an error is returned in case the verification fails.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|-------------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement feature ID to validated |
| dip_Boolean * | verdict | Pointer to the boolean verdict |

SEE ALSO

MeasurementForge

Allocate the data of a measurement data structure

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementForge ( measurement, featureID, objectID )
```

FUNCTION

This function forges a measurement data structure, that has been created with MeasurementNew. The featureID array should contain the IDs of the features to be performed. The vadility of these IDs is checked by comparing them with the IDs of registered measurement functions (see MeasurementFeatureRegister). The objectID array contains the IDs (i.e. labels) of the objects on which the features are to be performed. (For example, the Measure function accepts as one of its arguments a label image, of which the intensity of each individual pixel represents the ID of the object to which that pixel belongs. These label values should in that case correspond to the values of objectID.)

The measurement structure can be regarded as a matrix spanned by the number of features along one axis, and the number of objects along the other. MeasurementForge allocates and initialises the internal structures to contain this matrix and the data required for each conbimation of measurement and object ID.

ARGUMENTS

| Data type | Name | Description |
|------------------|-------------|-----------------------------------|
| dip_Measurement | measurement | Measurement structure |
| dip_IntegerArray | featureID | Array of measurement function IDs |
| dip_IntegerArray | objectID | Array of Object IDs |

FUNCTION

This function obtains the number of object IDs belonging to the featureID measurement function ID in the measurement structure. See MeasurementForge for a (brief) explination of the measurement data structure.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|---|
| dip_Measurement | measurement | Measurement data structure |
| dip_int * | objects | Pointer to an integer containing the number of object |
| | | IDs |

SEE ALSO

Measure, MeasurementNew, MeasurementObjects

MeasurementObjectData

Object data access function

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementObjectData ( measurement, featureID, objectID, data,
verdict )
```

FUNCTION

The MeasurementObjectData, MeasurementObjectValue and MeasurementFeatureDescription functions provide access to the functions that are registered by each measurement function. See also MeasurementFeatureRegister.

The Object data is the data allocated by a measurement function for internal purposes, for example to store intermediate results. Its format is free. Therefore, the use of this function is only meaningful for a particular measurement function itself. To access the measurement values of a measurement function, use MeasurementObjectValue.

The verdict parameter provides a means to test whether featureID or objectID are valid within the context of measurement. If one of them is invalid, and verdict is not zero, *verdict is set to DIP_FALSE, otherwise its value is DIP_TRUE. If verdict is zero, MeasurementObjectData produces an error when either featureID or objectID is invalid.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|-------------|--|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| $\mathtt{dip}_{-}\mathtt{int}$ | objectID | Object ID |
| void ** | data | Pointer to the internal measurement data pointer |
| dip_Boolean * | verdict | Pointer to a boolean containing validation |
| | | information |

MeasurementObjects

Get an object ID array

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementObjects ( measurement, featureID, objectID,
resources )
```

FUNCTION

This function obtains an array of object IDs belonging to the featureID measurement function in the measurement structure. See MeasurementForge for a (brief) explination of the measurement data structure.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-------------|--|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| dip_IntegerArray * | objectID | Pointer to an object ID array |

MeasurementObjectValid

Verify an object ID

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementObjectValid ( measurement, featureID, objectID,
verdict )
```

FUNCTION

This function determines whether the object ID objectID, belonging to the measurement function ID featureID, is a valid object ID, by comparing objectID to the object IDs belonging to the featureID in measurement. If verdict is not zero, the result (DIP_TRUE or DIP_FALSE) is stored in verdict, otherwise an error is returned in case the verification fails.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|--|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| dip_int | objectID | Object ID |
| dip_Boolean * | verdict | Pointer to a boolean containing the validation verdict |

MeasurementObjectValue

Object value access function

SYNOPSIS

#include "dip_measurement.h"
dip_Error dip_MeasurementObjectValue (measurement, featureID, objectID,
data, format, resources)

FUNCTION

The MeasurementObjectData, MeasurementObjectValue and MeasurementFeatureDescription functions provide access to the functions that are registered by each measurement function. See also MeasurementFeatureRegister.

The MeasurementObjectValue function provides access to the measurement values produced by the featureID measurement function measured on the objectID labeled object. The format of data is specified by format.

ARGUMENTS

| Data type | Name | Description |
|-------------------------------|-------------|-----------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_int | featureID | Measurement function ID |
| dip_int | objectID | Object ID |
| void ** | data | Pointer to data pointer |
| dipf_MeasurementValueFormat * | format | Pointer to the data format label |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

Measurement data formats

| Name | Description |
|------------------------------------|-----------------------------------|
| DIP_MSR_VALUE_FORMAT_INTEGER | Integer scalar data format |
| DIP_MSR_VALUE_FORMAT_FLOAT | Float scalar data format |
| DIP_MSR_VALUE_FORMAT_INTEGER_ARRAY | Integer array data format |
| DIP_MSR_VALUE_FORMAT_FLOAT_ARRAY | Float array data format |
| DIP_MSR_VALUE_FORMAT_IMAGE | Data is formatted as an dip_Image |

MeasurementRead

Read measurement results from a file

SYNOPSIS

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementRead ( measurement, filename, format,
addExtensions, recognised )
```

FUNCTION

This function reads measurement data from a file and puts it in measurement. measurement must be allocated before calling this function. If format is 0, all different MeasurementRead functions are called in sequence until the correct format has been found. If you know the format, get the correct format ID through the registry functions.

The boolean addExtensions specifies whether MeasurementRead should try to add file format extensions to filename, if the registered file format reader fails to recognise filename straight away. The extensions are provided by the registered file readers.

If recognised is not zero, MeasurementRead will set it to DIP_TRUE when it has been able to read filename, and it will set it to DIP_FALSE when it is not able to read the file. No error will be generated in this case.

NOTE

There are currently no measurement reading functions, so this function will always fail.

ARGUMENTS

| Data type | Name | Description |
|-----------------|---------------|--|
| dip_Measurement | measurement | Measurement data structure |
| dip_String | filename | File name to read from |
| dip_int | format | ID of file format |
| dip_Boolean | addExtensions | Add extensions when looking for the file |
| dip_Boolean * | recognised | Set to DIP_TRUE if the file was found |

SEE ALSO

MeasurementToHistogram

Creats a histogram for a measurement

SYNOPSIS

```
#include "dip_measurement.h" #include "dip_distribution.h"
dip_Error dip_MeasurementToHistogram ( histogram, measurement, featureID, binSize, maximum, minimum, percentage, addMeasurement )
```

DATA TYPES

integer

FUNCTION

This function creates a (possibly multi-dimensional) histogram with the measurement results of one feature. If addMeasurement is DIP_TRUE, new data points are added to the existing histogram, and binSize, maximum, minimum and percentage input arguments are ignored. Otherwise, histogram is destroyed and recreated according to the chosen values for binSize, maximum, minimum and percentage. If percentage is DIP_TRUE, maximum and minimum represent a percentage of the data range, otherwise they represent absolute values. If maximum or minimum are NULL, the maximum or minimum of the data is used.

ARGUMENTS

| Data type | Name | Description |
|------------------|----------------|--|
| dip_Distribution | histogram | Output histogram |
| dip_Measurement | measurement | Measurement data |
| dip_IntegerArray | featureID | List of feature IDs to use |
| dip_FloatArray | binSize | Size of the histogram bins |
| dip_FloatArray | maximum | Maximum value represented in the histogram |
| dip_FloatArray | minimum | Minimum value represented in the histogram |
| dip_Boolean | percentage | Whether maximum and minimum are percentages |
| dip_Boolean | addMeasurement | Whether to add data to histogram or create a |
| | | new one |

DIP*lib* function reference 501

MeasurementToImage

Exports the data in a measurement structure to an image

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_MeasurementToImage ( measurement, out, measurementIDs, objects
)
```

DATA TYPES

float

FUNCTION

This function creates an image and writes the measurement data to it as if it were a table, measurements along the first dimension, objects along the second dimension.

ARGUMENTS

| Data type | Name | Description |
|------------------|----------------|-----------------------------------|
| dip_Measurement | measurement | Input measurement |
| dip_Image | out | Output image |
| dip_IntegerArray | measurementIDs | List of measurement IDs to export |
| dip_IntegerArray | objects | List of object IDs to export |

SEE ALSO

 ${\tt Measure}, {\tt ObjectToMeasurement}, {\tt MeasurementToHistogram}$

MeasurementWrite

Write measurement results to a file

SYNOPSIS

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementWrite ( measurement, filename, format, labels )
```

FUNCTION

This function writes measurement data to a file, overwriting any other file with the same name. Get the format ID through the registry functions. If format is 0, CSV is used.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|----------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_String | filename | File name to write to |
| dip_int | format | ID of file format |
| dip_Boolean | labels | DIP_TRUE to write labels to file |

SEE ALSO

 ${\tt Measure,\,MeasurementRead,\,MeasurementWriteCSV,\,MeasurementWriteHTML,\,MeasurementWriteText}$

MeasurementWriteCSV

Write measurement results to a CSV file

SYNOPSIS

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementWriteCSV (measurement, filename, separator, labels)
```

FUNCTION

This function writes the measurement results to a comma separated values (CSV) file, overwriting any other file with the same name.

This function calls MeasurementWriteText with the proper settings.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|----------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_String | filename | File name to write to |
| char * | separator | Characters to separate values |
| dip_Boolean | labels | DIP_TRUE to write labels to file |

SEE ALSO

 ${\tt Measure}, \, {\tt MeasurementWrite}, \, {\tt MeasurementWriteText}$

MeasurementWriteHTML

Write measurement results to an HTML file

SYNOPSIS

#include "dipio_measurement.h"
dip_Error dipio_MeasurementWriteHTML (measurement, filename, separator, labels)

FUNCTION

This function writes the measurement results to a formatted HTML file, overwriting any other file with the same name.

ARGUMENTS

| Data type | Name | Description |
|-----------------|-------------|----------------------------------|
| dip_Measurement | measurement | Measurement data structure |
| dip_String | filename | File name to write to |
| char * | separator | Characters to separate values |
| dip_Boolean | labels | DIP_TRUE to write labels to file |

SEE ALSO

Measure, MeasurementWrite

MeasurementWriteText

Write measurement results as readable text

SYNOPSIS

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementWriteText ( measurement, fp, options )
```

FUNCTION

This function saves/prints the results of a measurement stored in the measurement data structure. Since it will save the results to the fp FILE pointer (which has to be opened before this function is called, and closed afterwards), the results can be printed to a screen (specify stdout as fp) or to a file.

The results are saved in a matrix, with a column for each measurement, and a row for each object. The first column contains the object ID. The options structure provides a means to adjust the formatting of the measurement data. Its separator variable specifies the column separator character, the rows are separated by a newline. If the labelAlign variable is DIP_TRUE, the separator is repeated such that the columns are aligned. If the labels variable is DIP_TRUE, the first row contains measurement labels, and info specifies whether or not the short description of each measurement function should be printed before the result matrix. If results is DIP_FALSE, the measurement values are not printed.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-------------|---|
| dip_Measurement | measurement | Measurement data structure |
| FILE * | fp | FILE pointer to which the results are saved |
| dipio_WriteTextFormat | options | Text formatting options |

The structure dipio_WriteTextFormat contains the following elements:

| Data type | Name | Description |
|-------------|------------|----------------------------|
| char * | separator | Column separator character |
| dip_Boolean | info | Write descriptio |
| dip_Boolean | labels | Write labels |
| dip_Boolean | results | Write values |
| dip_Boolean | labelAlign | Align columns |

SEE ALSO

Measure, MeasurementWrite

Median

statistics function

SYNOPSIS

dip_Error dip_Median (in, mask, out, ps)

DATA TYPES

binary, integer, float, complex

FUNCTION

Calculates the median of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| ${\tt dip_Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_BooleanArray | ps (0) | Dimensions to project |

SEE ALSO

From images to scalars

Sum, Mean, Variance, StandardDeviation, MeanModulus, SumModulus, MeanSquareModulus, Maximum, Minimum, Percentile

MedianFilter

Non-linear smoothing filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_MedianFilter ( in, out, se, boundary, param, shape )
```

DATA TYPES

integer, float

FUNCTION

Median filter with different filter shapes.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|------------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | se | Custom filter shape (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Filter shape |

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

SEE ALSO

PercentileFilter, Uniform, Sigma

${\tt MemoryCopy}$

Copy memory blocks

SYNOPSIS

void dip_MemoryCopy(in, out, number)

FUNCTION

Copy a memory block

ARGUMENTS

| Data type | Name | Description |
|-----------|--------|-------------------------------------|
| void * | in | pointer to memory source block |
| void * | out | pointer to memory destination block |
| dip_int | number | number of bytes to be copied |

NOTE

The behaviour of this function is undefined when the in and out blocks overlap.

MemoryFree

Free a chunk of memory

SYNOPSIS

dip_Error dip_MemoryFree(pointer)

FUNCTION

Frees a chunk of memory.

ARGUMENTS

| Data type | Name | Description |
|-----------|---------|---|
| void * | pointer | pointer to an allocated chunk of memory |

SEE ALSO

MemoryNew, MemoryReallocate, MemoryFunctionsSet

MemoryFunctionsSet

Sets memory allocation functions

SYNOPSIS

FUNCTION

Sets the memory allocation functions used by DIPlib.

ARGUMENTS

| Data type | Name | Description |
|------------------------------|--------------------------|-----------------------|
| dip_MemoryNewFunction | MemoryNewFunction | pointer to a memory |
| | | allocation function |
| dip_MemoryReallocateFunction | MemoryReallocateFunction | pointer to a memory |
| | | reallocation function |
| dip_MemoryFreeFunction | MemoryFreeFunction | pointer to a memory |
| | | freeing function |

NOTE

The three allocation functions are defined as follows:

```
typedef void* (*dip_MemoryNewFunction)(size_t size)
typedef void* (*dip_MemoryReallocateFunction)(void *ptr, size_t size)
typedef void (*dip_MemoryFreeFunction)(void *ptr)
And are by default set to malloc, realloc and free.
```

SEE ALSO

MemoryNew, MemoryReallocate, MemoryFree

MemoryNew

513

Allocate and track memory

SYNOPSIS

dip_Error dip_MemoryNew(pointer, size, resources)

FUNCTION

Allocates a chunk of memory, and adds a reference to the chunk to the list of tracked resources.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--|
| void ** | pointer | pointer to the memory chunk pointer |
| size_t | size | size of the memory chunk in bytes |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

MemoryReallocate, MemoryFree, MemoryFunctionsSet

MemoryReallocate

Reallocate a chunk of memory

SYNOPSIS

dip_Error dip_MemoryReallocate (pointer, newsize, resources)

FUNCTION

Reallocates a chunk of memory, to change its size. resources must be the dip_Resources structure used in the call to MemoryNew when pointer was allocated.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--|
| void ** | pointer | pointer to the memory chunk pointer |
| size_t | newsize | size of the memory chunk in bytes |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

MemoryNew, MemoryFree, MemoryFunctionsSet

mErf

mathematical function

SYNOPSIS

dip_float dipm_Erf (x)

FUNCTION

Computes the error function of the input value.

ARGUMENTS

| Data type | Name | Description |
|-----------|------|-------------|
| dip_float | х | Input value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErfc, mGammaP, mGammaQ

mErfc

mathematical function

SYNOPSIS

dip_float dipm_Erfc (x)

FUNCTION

Computes the complementary error function of the input value.

ARGUMENTS

| Data type | Name | Description |
|----------------|------|-------------|
| $dip_{-}float$ | X | Input value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mGammaP, mGammaQ

mExp10

517

mathematical function

SYNOPSIS

dip_float dipm_Exp10 (x)

FUNCTION

Computes the base ten exponent of the input value.

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|-------------|
| $dip_{-}float$ | value | Value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp2, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mErfc, mGammaP, mGammaQ

mExp2

mathematical function

SYNOPSIS

dip_float dipm_Exp2 (x)

FUNCTION

Computes the base two exponent of the input value.

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|-------------|
| $dip_{-}float$ | value | Value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mErfc, mGammaP, mGammaQ

mFraction

mathematical function

SYNOPSIS

dip_float dipm_Fraction (x)

FUNCTION

Computes the fraction of the input value.

ARGUMENTS

| Data type | Name | Description |
|----------------|------|-------------|
| $dip_{-}float$ | X | Input value |

SEE ALSO

mTruncate, mNearestInt, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mErfc, mGammaP, mGammaQ

mGammaP

mathematical function

SYNOPSIS

dip_float dipm_GammaP (a, x)

FUNCTION

Computes the incomplete gamma function of the input value.

ARGUMENTS

| Data type | Name | Description |
|-----------|------|-------------|
| dip_float | a | A |
| dip_float | х | Input value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mErfc, mGammaQ

mGammaQ

521

mathematical function

SYNOPSIS

dip_float dipm_GammaQ (a, x)

FUNCTION

Computes the complementary incomplete gamma function of the input value.

ARGUMENTS

| Data type | Name | Description |
|-----------|------|-------------|
| dip_float | a | A |
| dip_float | х | Input value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mErfc, mGammaP

Min

arithmetic function

SYNOPSIS

dip_Error dip_Min (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function computes $\mathtt{out} = \min(\mathtt{in1}\ , \mathtt{in2})$ on a pixel by pixel basis. The data types of the $\mathtt{in1}$ and $\mathtt{in2}$ image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description | |
|----------------------------------|------|--------------|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input | |
| $dip_{-}Image$ | in2 | Second input | |
| dip_Image | out | Output | |

SEE ALSO

Max, MaxFloat, MinFloat

MinFloat

arithmetic function

SYNOPSIS

dip_Error dip_MinFloat (in, out, constant)

DATA TYPES

binary, integer, float

FUNCTION

This function computes out = min(in, constant) on a pixel by pixel basis. The data types of the in1 image and constant may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_float | constant | Constant |

SEE ALSO

Max, MaxFloat, Min

Minima

Detects local minima

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_Minima ( in, mask, out, connectivity, booleanOutput )
```

DATA TYPES

integer, float

FUNCTION

This function detects local minima.

The algorithm finds a connected set of pixels with identical value, an no neighbours with lower value. This set is a local minimum and its pixels are set to 1 in the output image. If booleanOutput is false, the output image is a labelled image.

This function differs from LocalMinima in that it marks every minimum. LocalMinima is able to filter out unimportant minima.

For images that have large plateaus (regions of constant value) that are not local minima, this function can be quite slow. For example, an image that is one everywhere except for a small valley somewhere. For such an image it is recommended to use the mask input, for example with the output of a threshold operation.

ARGUMENTS

| Data type | Name | Description |
|-------------|---------------|-----------------------------|
| dip_Image | in | Input image |
| dip_Image | mask | Mask image |
| dip_Image | out | Binary output image |
| dip_int | connectivity | Connectivity |
| dip_Boolean | booleanOutput | Give a binary output image? |

NOTE

If you are looking for the old version of Minima, it is still available through the following combination of commands:

```
dip_Erosion( in, out, se, boundary, param, shape );
dip_Equal( in, out, out );
```

SEE ALSO

 ${\tt Maxima, Subpixel Minima, Local Minima, Seeded Watershed, Grow Regions}$

Minimum

statistics function

SYNOPSIS

dip_Error dip_Minimum (in, mask, out, ps)

DATA TYPES

binary, integer, float

FUNCTION

Calculates the minimum of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask |
| dip_Image | out | Output |
| dip_BooleanArray | ps (0) | Dimensions to project |

SEE ALSO

Mirror

Mirrors an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Mirror ( in, out, mirror )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function mirrors the pixels in those dimensions of image as specified by mirror.

ARGUMENTS

| Data type | Name | Description |
|---|--------|--------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | in | Input image |
| dip_Image | out | Output image |
| dip_BooleanArray | mirror | Mirror flags |

SEE ALSO

Map

mLnGamma

mathematical function

SYNOPSIS

dip_float dipm_LnGamma (x)

FUNCTION

Computes the natural logarithm of the gamma function of the input value.

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|-------------|
| $dip_{-}float$ | value | Value |

SEE ALSO

mTruncate, mFraction, mNearestInt, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mErf, mErfc, mGammaP, mGammaQ

529

mLog2

mathematical function

SYNOPSIS

dip_float dipm_Log2 (x)

FUNCTION

Computes the base two logarithm of the input value.

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|-------------|
| $dip_{-}float$ | value | Value |

SEE ALSO

mNearestInt

mathematical function

SYNOPSIS

 $dip_float dipm_NearestInt (x)$

FUNCTION

Computes the nearest int of the input value.

ARGUMENTS

| Data type | Name | Description | |
|----------------|------|-------------|--|
| $dip_{-}float$ | X | Input value | |

SEE ALSO

mTruncate, mFraction, mSign, mExp2, mExp10, mLog2, mSinc, mReciprocal, mBesselJ0, mBesselJ1, mBesselJN, mBesselY0, mBesselY1, mBesselYN, mLnGamma, mErf, mErfc, mGammaP, mGammaQ

Modulo

Arithmetic function

SYNOPSIS

dip_Error dip_Modulo (in, out, period)

DATA TYPES

${\bf integer}$

FUNCTION

Computes the modulo of the input image values, by computing the remainder of the the division of the input image values with period.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------|-------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_int | period | Period |

SEE ALSO

Div, DivFloat, DivComplex, Reciprocal

Modulus

Arithmetic function

SYNOPSIS

dip_Error dip_Modulus (in, out)

DATA TYPES

binary, integer, float, **complex**

FUNCTION

Computes the modulus of the input image values, and outputs a float typed image.

ARGUMENTS

| Data type | Name | Description | |
|----------------|------|-------------|--|
| $dip_{-}Image$ | in | Input | |
| dip_Image | out | Output | |

SEE ALSO

Phase, Real, Imaginary

MonadicFrameWork

FrameWork for monadic operations

SYNOPSIS

 $\label{lem:condition} \begin{tabular}{ll} $\tt dip_Error \ dip_MonadicFrameWork \ (in, out, processBoundary, processBorder, process) \end{tabular}$

FUNCTION

This function is a frontend on the SeparableFrameWork. It provides an easier interface for filters that only need to scan an image once. The dimension in which the image should be scanned can be specified or left to MonadicFrameWork by specifying the dimension with DIP_MONADIC_OPTIMAL_DIMENSION.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------------|-----------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_Boundary | processBoundary | ProcessBoundary |
| dip_int | processBorder | ProcessBorder |
| dip_FrameWorkProcess | process | Process |

SEE ALSO

 ${\tt SeparableFrameWork}, {\tt SingleOutputFrameWork}$

${\tt MorphologicalGradientMagnitude}$

Morphological edge detector

SYNOPSIS

#include "dip_morphology.h"
dip_Error dip_MorphologicalGradientMagnitude (in, out, se, boundary, param,
shape, edgeType)

DATA TYPES

 $integer,\,float\\$

FUNCTION

The same as MorphologicalRange.

ARGUMENTS

| Data type | Name | Description |
|---|----------|----------------------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | out | Output |
| $\mathtt{dip}_{-}\mathtt{Image}$ | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |
| dip_MphEdgeType | edgeType | edgeType |

SEE ALSO

 ${\tt Morphological Range, Lee, MultiScale Morphological Gradient, Tophat}$

MorphologicalRange

Morphological edge detector

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_MorphologicalRange ( in, out, se, boundary, param, shape,
edgeType )
```

DATA TYPES

integer, float

FUNCTION

Implements a morphological edge detector based on the difference of two complementary morphological operations. These can be chosen through the edgeType parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |
| dip_MphEdgeType | edgeType | edgeType |

The enumerator ${\tt dip.FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

The enumerator ${\tt dip_MphEdgeType}$ contains the following constants:

| Name | Description | |
|-----------------|---|--|
| DIP_MPH_TEXTURE | Response is limited to edges in texture | |
| DIP_MPH_OBJECT | Response is limited to object edges | |
| DIP_MPH_BOTH | All edges produce equal response | |

MorphologicalReconstruction

Morphological filter

SYNOPSIS

#include "dip_morphology.h"
dip_Error dip_MorphologicalReconstruction (marker, mask, out, connectivity)

DATA TYPES

integer, float

FUNCTION

Dilation of the image marker, constrained by the image mask. out will be smaller or equal to mask. The image is grown according to the connectivity parameter. See The connectivity parameter for more information.

ARGUMENTS

| Data type | Name | Description |
|---|--------------|--------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | marker | Marker input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask | Mask input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_int | connectivity | Connectivity |

Dilation, BinaryPropagation, AreaOpening

MorphologicalSmoothing

Morphological smoothing filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_MorphologicalSmoothing ( in, out, se, boundary, param, shape,
flags )
```

DATA TYPES

integer, float

FUNCTION

Implements a morphological smoothing based on the sequence of two complementary morphological operations. These can be chosen through the dipf_MphSmoothing parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |
| dipf_MphSmoothing | flags | flags |

The enumerator ${\tt dip.FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |

MorphologicalThreshold

Morphological smoothing filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_MorphologicalThreshold ( in, out, se, boundary, param, shape,
edgeType )
```

DATA TYPES

integer, float

FUNCTION

Implements a morphological smoothing based on the average of two complementary morphological operations. These can be chosen through the edgeType parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |
| dip_MphEdgeType | edgeType | edgeType |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

The enumerator ${\tt dip_MphEdgeType}$ contains the following constants:

| Name | Description | |
|-----------------|---|--|
| DIP_MPH_TEXTURE | Response is limited to edges in texture | |
| DIP_MPH_OBJECT | Response is limited to object edges | |
| DIP_MPH_BOTH | All edges produce equal response | |

MultiScaleMorphologicalGradient

Morphological edge detector

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_MultiScaleMorphologicalGradient ( in, out, se, boundary,
upperSize, lowerSize, shape )
```

DATA TYPES

integer, float

FUNCTION

This function computes the average morphological gradient over a range of scales bounded by upperSize and lowerSize. The morphological gradient is computed as the difference of the dilation and erosion of the input image at a particular scale, eroded by an erosion of one size smaller. At the lowest scale, the size of the structuring element is 2 * upperSize + 1.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-----------|-----------------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_int | upperSize | Upper size of structuring element |
| dip_int | lowerSize | Lower size of structuring element |
| dip_FilterShape | shape | Structuring element |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

${\tt NeighbourIndicesListMake}$

Get indices to direct neighbours

SYNOPSIS

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourIndicesListMake ( stride, connectivity, indices, resources )
```

FUNCTION

A list indices is created with the relative indices to the direct neighbours of a pixel in an image whose strides are given by stride. How many direct neighbours are returned is controlled by connectivity, see The connectivity parameter for the available values and their meaning.

indices is allocated and tracked in resources.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------------|--|
| dip_IntegerArray | stride | Stride array |
| dip_int | connectivity | Connectivity |
| dip_IntegerArray * | indices | Output neighbour indices |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

NeighbourListMake

Get list of direct neighbours

SYNOPSIS

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListMake ( ndims, connectivity, coords, resources )
```

FUNCTION

A list coords is created with the relative coordinates to the direct neighbours of a pixel in an ndims-dimensional image. How many direct neighbours are returned is controlled by connectivity, see The connectivity parameter for the available values and their meaning. coords is allocated and tracked in resources.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|--------------|-----------------------------------|
| dip_int | ndims | Image dimensionality |
| dip_int | connectivity | Connectivity |
| dip_CoordinateArray * | coords | Output neighbour coordinates |
| dip_Resources | resources | Resources tracking structure. See |

NeighbourListMakeChamfer

Get list of neighbours based on Chamfer metric

SYNOPSIS

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListMakeChamfer ( pixelsize, maxdistance, coords,
distance, resources )
```

FUNCTION

A list coords is created with the relative coordinates to the neighbours of a pixel in an pixelsize->size-dimensional image. Here, neighbours are all pixels within a maxdistance distance. pixelsize gives the size of a pixel, and hence controls the size of the neighbourhood with maxdistance. Anisotropic pixel grids are supported. distance contains the distance to each of the neighbours in coords.

Distances between two pixels are taken to be the Euclidean distance. There are better metrics described in the literature for small neighbourhoods, that yield a more isotropic measure when compounded over longer distances. These are not implemented in this function.

coords and distance are allocated and tracked in resources.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-------------|---|
| dip_FloatArray | pixelsize | Physical dimensions of the pixels |
| dip_int | maxdistance | Maximum distance to which select neighbours |
| dip_CoordinateArray * | coords | Output neighbour coordinates |
| dip_FloatArray * | distance | Output distances to neighbours |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

SEE ALSO

NeighbourListMakeImage

Get list of neighbours based on metric in image

SYNOPSIS

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListMakeImage ( metric, coords, distance, resources )
```

FUNCTION

A list coords is created with the relative coordinates to the neighbours of a pixel in an image, with dimensionality as in metric. metric is an image that specifies the distance to each of the neighbours. This image must be odd in size, the centre pixel is the origin of the neighbourhood. Any pixel with value 0 is not considered part of the neighbourhood. distance contains the distance to each of the neighbours in coords.

Distances between two pixels are taken to be the Euclidean distance. There are better metrics described in the literature for small neighbourhoods, that yield a more isotropic measure when compounded over longer distances. These are not implemented in this function.

coords and distance are allocated and tracked in resources.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-----------|---|
| dip_Image | metric | Image whose pixel values indicate the neighbour |
| | | distance |
| dip_CoordinateArray * | coords | Output neighbour coordinates |
| dip_FloatArray * | distance | Output distances to neighbours |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

NormaliseSum

557

Normalise the sum of the pixel values

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_NormaliseSum ( in, out, newSum )
```

DATA TYPES

binary, integer, **float**

FUNCTION

This function normalizes the sum of the pixel values in in to newSum, and puts the result in out.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------|--------------|
| $dip_{-}Image$ | in | Input image |
| ${\tt dip_Image}$ | out | Output image |
| dip_float | newSum | New sum |

NotEqual

Compare grey values in two images

SYNOPSIS

dip_Error dip_NotEqual (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function sets each pixel in out to "true" when corresponding pixels in in1 and in2 are different. This is the same as Compare with the DIP_SELECT_NOT_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to the functionality of NotZero, but with more options.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| ${\tt dip_Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| dip_Image | out | Output |

SEE ALSO

Compare, Threshold, Equal, Greater, Lesser, NotGreater, NotLesser, SelectValue, NotZero

NotGreater

Compare grey values in two images

SYNOPSIS

dip_Error dip_NotGreater (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function sets each pixel in out to "true" when for corresponding pixels in1 <= in2. This is the same as Compare with the DIP_SELECT_LESSER_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

ARGUMENTS

| Data type | Name | Description |
|---|------|--------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| dip_Image | out | Output |

SEE ALSO

Compare, Threshold, Equal, Greater, Lesser, NotEqual, NotLesser, SelectValue, NotZero

NotLesser

Compare grey values in two images

SYNOPSIS

dip_Error dip_NotLesser (in1, in2, out)

DATA TYPES

binary, integer, float

FUNCTION

This function sets each pixel in out to "true" when for corresponding pixels in1 >= in2. This is the same as Compare with the DIP_SELECT_GREATER_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| ${\tt dip_Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| $dip_{-}Image$ | out | Output |

SEE ALSO

NotZero

Point Operation

SYNOPSIS

```
#include "dip_point.h"
dip_Error dip_NotZero ( in, out )
```

DATA TYPES

integer, float

FUNCTION

This function returns a binary image with value 1 where in != 0 and value 0 elsewhere. The opposite can be accomplished with SelectValue: dip_SelectValue(in,out,0);.

ARGUMENTS

| Data type | Name | Description |
|--------------------|------|--------------|
| ${\tt dip_Image}$ | in | Input image |
| dip_Image | out | Output image |

SEE ALSO

Threshold, SelectValue, Compare, RangeThreshold

ObjectToMeasurement

Convert object label value to measurement value

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_ObjectToMeasurement ( object, intensity, out, connectivity,
objectID, featureID, measurementDim )
```

DATA TYPES

objectIm: integer intensityIm: integer, float

FUNCTION

This function produces an output image which pixel intensities are equal to the measurement value that the featureID measurement function measured on the object who label is defined by the pixel intensity of the corresponding pixel in object. This function is therefore useful to select (i.e. threshold) objects on basis of a measurement perfomed on the object. intensity provides pixel intensity information for measurements that require pixel intensity information of the objects, whose shape is defined by object.

The list of object IDs on which the measurements have to be performed is specified by objectID. If it is zero, ObjectToMeasurement will call GetObjectLabels to obtain a list of all non-zero values in objectIm.

If the featureID measurement function produces an array of measurement values, measurementDim will be used to select the desired array element.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------------|--|
| dip_Image | object | Object label image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | intensity | Object intensity image |
| $dip_{-}Image$ | out | Output image |
| dip_int | connectivity | Connectivity of object's contour pixels, see The |
| | | connectivity parameter |
| dip_IntegerArray | objectID | Array of Object IDs |
| dip_int | featureID | Measurement function ID |
| dip_int | measurementDim | Measurement results array index |

OneDimensionalSearch

Numerical algorithm

SYNOPSIS

```
#include "dip_numerical.h"
dip_Error dip_OneDimensionalSearch ( result, min, max, tol, func, dfunc,
data, searchfor )
```

FUNCTION

This function implements a numerical line-search for either the minimum or zero-crossing of a function. The obejctive is searched for in the range specified by min and man with a tolerance of tol. The search methods are based on Brent's algorithm. The dfunc parameter is preparation for support of search algorithms using derivative information. This is not supported in the current implementation, and dfunc should be set to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|-----------------------------------|
| dip_float * | result | Result value |
| dip_float | min | Minimum value of search domain |
| dip_float | max | Maximum value of search domain |
| dip_float | tol | Tolerance |
| dip_OneDimensionalSearchFunction | func | Function |
| dip_OneDimensionalSearchFunction | dfunc | Derivative function |
| void * | data | User-supplied Data passed to func |
| | | and dfunc |
| dipf_OneDimensionSearch | searchfor | Search for minimum of |
| | | zero-crossing |

DIP*lib* function reference

Opening

Morphological opening operation

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Opening ( in, out, se, boundary, param, shape )
```

DATA TYPES

integer, float, binary

FUNCTION

Grey-value opening with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |

The enumerator ${\tt dip_FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

ovl.h

Call an overloaded function

SYNOPSIS

```
dip_DataType ovlDataType = [current data type];
[#define DIP_OVL_ASSIGN [assignment target]]
#define DIP_OVL_FUNC [function base name]
#define DIP_OVL_ARGS [argument list]
#define DIP_OVL_ALLOW [type identifiers]
#include "dip_ovl.h"
```

FUNCTION

Call a type specific function based on the data type stored in the ovlDataType variable. The base name of the function is passed to dip_ovl.h by defining DIP_OVL_FUNC. The argument list is passed by defining DIP_OVL_ARGS. By defining DIP_OVL_ALLOW the list of data types for which overloading is possible can be controlled. If DIP_OVL_ALLOW is not defined, all data types are allowed. The list is specified by a logical OR of identifier and identifier group flags, see the table at DIPlib's data types. The code executed by dip_ovl.h is the following:

```
/* if ovlDataType is in the list specified by DIP_OVL_ALLOW */
DIPXJ( DIP_FUNC(DIP_OVL_FUNC,ovlDataType's extension) DIP_OVL_ARGS );
/* if ovlDataType is not in the list specified by DIP_OVL_ALLOW */
DIPSJ( DIP_E_DATA_TYPE_NOT_SUPPORTED );
```

DIP_FUNC is described in macros.h. Note that there are no brackets around DIP_OVL_ARGS, so they must be included in DIP_OVL_ARGS itself. If ovlDataType is one of the binary types, DIP_OVL_BINARY_ARGS can be defined to override DIP_OVL_ARGS.

If DIP_OVL_ASSIGN is defined, the following code will be executed by dip_ovl.h instead of the code shown above:

```
DIP_OVL_ASSIGN DIP_FUNC(DIP_OVL_FUNC, ovlDataType's extension) DIP_OVL_ARGS;
```

Note that to actually perform an assignment the "=" operator must be included in the definition of DIP_OVL_ASSIGN itself. DIP_OVL_BINARY_ASSIGN overrides DIP_OVL_ASSIGN if ovlDataType is one of the binary data types.

PaintBox

Paint a box

SYNOPSIS

```
#include "dip_paint.h"
dip_Error dip_PaintBox ( im, length, orign, amplitude )
```

DATA TYPES

binary, integer, **float**, complex

FUNCTION

Paints an box object in the image by replacing the values of the pixels in im that lie within the box (as specified by length and origin) with amplitude, and leaving the other pixel values untouched.

ARGUMENTS

| Data type | Name | Description |
|---|-----------|-----------------------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | im | Image |
| dip_FloatArray | length | Length array |
| dip_FloatArray | origin | Origin array |
| dip_float | amplitude | Pixel value of the painted ellips |

SEE ALSO

PaintEllipsoid, PaintDiamond

PaintDiamond

Paint a diamond-shaped object

SYNOPSIS

```
#include "dip_paint.h"
dip_Error dip_PaintDiamond ( im, length, orign, amplitude )
```

DATA TYPES

binary, integer, **float**, complex

FUNCTION

Paints a diamond-shaped object in the image by replacing the values of the pixels in im that lie within the diamond (as specified by length and origin) with amplitude, and leaving the other pixel values untouched.

ARGUMENTS

| Data type | Name | Description |
|---|-----------|-----------------------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | im | Image |
| dip_FloatArray | length | Length array |
| dip_FloatArray | origin | Origin array |

PaintEllipsoid

Paint an ellipsoid

SYNOPSIS

```
#include "dip_paint.h"
dip_Error dip_PaintEllipsoid ( im, radius, orign, scale, amplitude )
```

DATA TYPES

binary, integer, **float**, complex

FUNCTION

Paints an elliptical object in the image by replacing the values of the pixels in im that lie within the ellips (as specified by diameter and origin) with amplitude, and leaving the other pixel values untouched.

ARGUMENTS

| Data type | Name | Description |
|---|-----------|-----------------------------------|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | im | Image |
| dip_FloatArray | radius | Diameter array |
| dip_FloatArray | origin | Origin array |
| dip_float | amplitude | Pixel value of the painted ellips |

PairCorrelation

Compute the pair correlation function

SYNOPSIS

#include "dip_analysis.h"
dip_Error dip_PairCorrelation (object, mask, dist, probes, length, sampling,
covariance)

DATA TYPES

binary, integer

FUNCTION

This function computes the pair correlation function of the different phases in object. If object is a binary image, the image is a regarded as a two phase image. In case object is of the integer type, the image is regarded as a labeled image, with each integer value encoding a phase. Optionally a mask image can be provided to select which pixels in object should be used to compute the pair correlation. The probes variable specifies how many random point pairs should be drawn to compute the function. Length specifies the maximum correlation length. The correlation function can be computed using a random (DIP_CORRELATION_ESTIMATOR_RANDOM) or grid method (DIP_CORRELATION_ESTIMATOR_GRID), as specified by sampling. Finally covariance

(DIP_CORRELATION_ESTIMATOR_GRID), as specified by sampling. Finally covariance determines whether only the correlations (DIP_FALSE) or the covarianances (DIP_TRUE) have to be computed.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|------------|----------------------------|
| ${\tt dip_Image}$ | object | Object image |
| $dip_{-}Image$ | mask | Mask image |
| dip_Distribution | dist | Ouput distribution |
| dip_int | probes | Number of probes |
| dip_int | length | Maximum correlation Length |
| dipf_CorrelationEstimator | sampling | Samplings method |
| dip_Boolean | covariance | Compute covariance |

PathOpening

Morphological filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error PathOpening ( grey, mask, out, length, closing, constrained )
```

DATA TYPES

binary, integer, float

FUNCTION

This function applies DirectedPathOpening in all possible directions and takes the supremum of all results. That is, it is the supremum of all possible openings with approximately linear structuring elements of length length.

The number of times that DirectedPathOpening is applied is given by ((3^D)-1)/2, with D the number of image dimensions. For example, in 2D there are 4 possible values for param: [length,0], [0,length], [length,length] and [length,-length] (note that, for example, [-length,0] produces the same result as [length,0]).

See DirectedPathOpening for more information.

ARGUMENTS

| Data type | Name | Description |
|---|-------------|--|
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | grey | Grey-value input image |
| dip_Image | mask | Mask image for ROI processing |
| dip_Image | out | Output image |
| dip_int | length | Length of structuring element (number of pixels) |
| dip_Boolean | closing | DIP_FALSE for path opening, DIP_TRUE for path closing |
| dip_Boolean | constrained | DIP_TRUE for constrained paths, DIP_FALSE for the original |
| | | path opening algorithm |

SEE ALSO

DirectedPathOpening, Opening, Closing, AreaOpening

Percentile

statistics function

SYNOPSIS

dip_Error dip_Percentile (in, mask, out, percentile, ps)

DATA TYPES

binary, integer, float, complex

FUNCTION

Calculates the perc percentile of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask |
| dip_Image | out | Output |
| dip_float | perc | Percentile |
| dip_BooleanArray | ps (0) | Dimensions to project |

PercentileFilter

Rank-order filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_PercentileFilter ( in, out, se, boundary, param, shape,
percentile )
```

DATA TYPES

integer, float

FUNCTION

Rank-order or percentile filter with different filter shapes.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------------|------------------------------|
| dip_Image | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_Image | se | Custom filter shape (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Filter shape |
| dip_float | percentile | Percentile (%) |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

PhysicalDimensionsIsIsotropic

Checks if the Physical Dimensions are isotropic

SYNOPSIS

dip_Error dip_PhysicalDimensionsIsIsotropic (physDims, verdict)

FUNCTION

This function checks whether the physical dimensions <code>physDims</code> are isotropic by checking that all its pixel dimensions and dimension units are equal to each other. If <code>verdict</code> is not zero, the result (<code>DIP_TRUE</code> or <code>DIP_FALSE</code>) is stored in <code>verdict</code>, otherwise an error is returned in case the verification fails.

ARGUMENTS

| Data type | Name | Description |
|------------------------|----------|------------------------------------|
| dip_PhysicalDimensions | physDims | Physical Dimensions data structure |
| dip_Boolean * | verdict | Verdict of the test |

SEE ALSO

PhysicalDimensionsNew, PhysicalDimensionsFree, PhysicalDimensionsCopy

PhysicalDimensionsNew

Allocates a new Physical Dimensions structure

SYNOPSIS

dip_Error dip_PhysicalDimensionsNew (newPhysDims, dimensionality, dims, orig, dimUnit, intensity, offset, intensUnit, resources)

FUNCTION

This function allocates a new Physical Dimensions structure.

A physical dimensions structure contains information about the physical dimensions of the data (of dimensionality dimension) in an image. It describes the position (orig) and size (dims) of a pixel in world coordinates and physical units (dimUnits), as well as the scaling (intensity) and offset (offset) of the pixel intensity in physical units (intensUnit).

Note that the initial values assigned by this function assume an isotropic pixel size. These values can be changed within the structure generated if this is not the case.

ARGUMENTS

| Data type | Name | Description |
|--------------------------|----------------|---|
| dip_PhysicalDimensions * | newPhysDims | Pointer to a new Physical Dimensions |
| | | data structure |
| dip_int | dimensionality | Dimensionality of the image |
| dip_float | dims | Initial value for dimensions along all |
| | | axes |
| dip_float | orig | Initial value for origin along all axes |
| char * | dimUnit | Initial value for dimensionUnits along |
| | | all axes |
| dip_float | intensity | Initial value for intensity |
| dip_float | offset | Initial value for offset |
| char * | intensUnit | Initial value for intensityUnit |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

The structure dip_PhysicalDimensions contains the following elements:

| Data type | Name | Description |
|-----------------|----------------|---|
| dip_FloatArray | dimensions | Dimensions of a pixel along each grid axis |
| dip_FloatArray | origin | Coordinates of the origin in physical units |
| dip_StringArray | dimensionUnits | Units for dimensions and origin |
| dip_float | intensity | Intensity scaling in physical units |
| dip_float | offset | Offset for intensity in physical units |
| dip_String | intensityUnit | Units for intensity and offset |
| dip_Resources | resources | Resource tracking; all elements within this |
| | | structure are tracked here |

PixelHeapFree

Destroy heap structure

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapFree ( heap )
```

FUNCTION

Frees all data associated to heap and sets heap to 0.

ARGUMENTS

| Data type | Name | Description |
|-----------------|------|--------------------|
| dip_PixelHeap * | heap | The heap structure |

SEE ALSO

PixelHeapNew, StablePixelHeapNew, PixelQueueNew, PixelHeapPush, PixelHeapPop, PixelHeapIsEmpty

PixelHeapIsEmpty

Query heap

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapIsEmpty ( heap, result )
```

FUNCTION

Checks to see if there are any items on the heap. See PixelHeapNew for information on the heap data structure.

ARGUMENTS

| Data type | Name | Description |
|---------------|--------|---|
| dip_PixelHeap | heap | The heap structure |
| dip_Boolean * | result | Set to true if there are no items in the heap |

SEE ALSO

PixelHeapNew, StablePixelHeapNew, PixelQueueNew, PixelHeapFree, PixelHeapPush, PixelHeapPop

PixelHeapNew

Create a new heap structure

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapNew ( heap, ndims, blocksize, order, resources )
```

FUNCTION

This function allocates space for a new dip_PixelHeap structure. Memory allocated is tracked in resources. The heap is dimensioned to hold pixels from an ndims-dimensional image, and initially enough space is allocated for blocksize elements. The heap will be expanded as necessary when used.

The heap stores the coordinates, the value and the pointer to a pixel in an image. Note that the value does not need to equal the data pointed to by the pointer. ndims can be set to zero, in which case no coordinates are stored; this does not affect the function of the value and the pointer.

A heap is a priority queue data structure. Just like a queue, items can be added (pushed) and subtracted (popped). However, in the priority queue the item popped is always the higherst priority one: either the one with the highest-valued item (order is DIP_GVSO_HIGH_FIRST) or lowest-valued item (order is DIP_GVSO_LOW_FIRST). However, identically-valued items are stored on the heap in unpredictable order. If this order is important (such as for the GrowRegions algorithm with integer-valued pixels, use a dip_StablePixelHeap instead. See StablePixelHeapNew for information on the stable heap structure.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|-----------|------------------------------------|
| dip_PixelHeap * | heap | The newly allocated heap structure |
| dip_int | ndims | Image dimensionality |
| dip_int | blocksize | Size of each allocation block |
| dipf_GreyValueSortOrder | order | Determines the heap's sort order |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

The dipf_GreyValueSortOrder enumeration consists of the following values:

| Name | Description |
|---------------------|--|
| DIP_GVSO_HIGH_FIRST | Process the pixels from high grey-value to low grey-value. |
| DIP_GVSO_LOW_FIRST | Process the pixels from low grey-value to high grey-value. |

IMPLEMENTATION

When the heap grows beyond its initial size, its capacity is doubled in size by reallocating the data blocks. However, when removing pixels from the queue, the heap is not shrunk. It is assumed that the dip_PixelHeap structure will be destroyed as soon as the algorithm using it terminates. Reducing the memory footprint of the heap therefore has no benefit.

SEE ALSO

 ${\tt StablePixelHeapNew,\ PixelQueueNew,\ PixelHeapFree,\ PixelHeapPush,\ PixelHeapPop,\ PixelHeapIsEmpty}$

PixelHeapPop

Pop item onto heap

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapPop ( heap, coords, pointer, value )
```

FUNCTION

Pops the next pixel from the heap. See PixelHeapNew for information on the heap data structure. coords is a pointer to an array of dip_ints, such as that obtained with dip_IntegerArray->array. It should have as many elements as the image dimensionality. If the stack was created with ndims set to 0, the coords pointer is ignored. coords, pointer and value can be NULL if you are not interested in either those values.

ARGUMENTS

| Data type | Name | Description | |
|---------------|---------|---|--|
| dip_PixelHeap | heap | The heap structure | |
| dip_int * | coords | Receives the coordinates of the popped item | |
| void ** | pointer | Receives the pointer of the popped item | |
| dip_sfloat * | value | Receives the value of the popped item | |

SEE ALSO

PixelHeapNew, StablePixelHeapNew, PixelQueueNew, PixelHeapFree, PixelHeapPush, PixelHeapIsEmpty

PixelHeapPush

Push item onto heap

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapPush ( heap, coords, pointer, value )
```

FUNCTION

Pushes a pixel onto the heap. See PixelHeapNew for information on the heap data structure. All 3 values coords, pointer and value are stored, except if the heap was created with ndims set to 0, in which case the coords pointer is ignored.

coords is a pointer to an array of dip_ints, such as that obtained with dip_IntegerArray->array. It should have as many elements as the image dimensionality. pointer is a pointer to any memory location, and value is the value to be used when sorting.

ARGUMENTS

| Data type | Name | Description | |
|---------------|---------|--------------------------|--|
| dip_PixelHeap | heap | The heap structure | |
| dip_int * | coords | Coordinates to be pushed | |
| void * | pointer | Pointer to be pushed | |
| dip_sfloat | value | Value to be pushed | |

PixelQueueIsEmpty

Query queue

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueueIsEmpty ( queue, result )
```

FUNCTION

Checks to see if there are any items on the queue. See PixelQueueNew for information on the queue data structure.

ARGUMENTS

| Data type | Name | Description | |
|----------------|--------|--|--|
| dip_PixelQueue | queue | The queue structure | |
| dip_Boolean * | result | Set to true if there are no items in the queue | |

SEE ALSO

 ${\tt PixelQueueNew}, {\tt PixelHeapNew}, {\tt StablePixelHeapNew}, {\tt PixelQueueFree}, {\tt PixelQueuePush}, {\tt PixelQueuePop}$

PixelQueueNew

Create a new queue structure

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueueNew ( queue, ndims, blocksize, resources )
```

FUNCTION

This function allocates space for a new dip_PixelQueue structure. Memory allocated is tracked in resources. The queue is dimensioned to hold pixels from an ndims-dimensional image, and initially enough space is allocated for blocksize elements. The queue will be expanded as necessary when used.

The queue stores the coordinates, and the pointer to a pixel in an image. ndims can be set to zero, in which case no coordinates are stored; this does not affect the function of the pointer.

A queue is a data structure to which items can be added (pushed) to the back, and subtracted (popped) from the front (FIFO - First In, First Out).

ARGUMENTS

| Data type | Name | Description |
|------------------|-----------|--|
| dip_PixelQueue * | queue | The newly allocated queue structure |
| dip_int | ndims | Image dimensionality |
| dip_int | blocksize | Size of each allocation block |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

IMPLEMENTATION

The queue is stored in an array whose size can be incressed at will. This is accomplished by a linked list of blocks, each one holds blocksize elements. When more space is needed, a new block is simply allocated. No data needs to be moved as would be necessary when using realloc to change the size of the array. Blocks on the front of the queue that become empty are freed.

SEE ALSO

 ${\tt Pixel Heap New,\ Pixel Queue Free,\ Pixel Queue Push,\ Pixel Queue Pop,\ Pixel Queue Is Empty}$

PixelQueuePop

Pop item from queue

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueuePop ( queue, coords, pointer, newiteration )
```

FUNCTION

Pops the next pixel from the queue. See PixelQueueNew for information on the queue data structure. coords is a pointer to an array of dip_ints, such as that obtained with dip_IntegerArray->array. It should have as many elements as the image dimensionality. If the queue was created with ndims set to 0, the coords pointer is ignored. coords and pointer can be NULL if you are not interested in either those values.

newiteration, when not NULL, will be set to DIP_TRUE if the pixel being popped is the first one in an iteration, or DIP_FALSE otherwise. When a new iteration starts, all pixels pushed onto the queue afterwards belong to the next iteration. This is useful in routines that use the queue for propagating boundaries, such as <code>GrowRegions</code>. First all boundary pixels are pushed onto the queue. The first iteration will need to process only these pixels, while at the same time push new pixels onto the queue for the second iteration. So after pushing all the initial boundary pixels onto the queue, the first iteration is started by popping the first pixel. All pixels pushed while processing this and the rest of the pixels will be pushed behind the "new iteration" marker. When the first pixel after this marker is popped, the newiteration boolean is set, so the program knows that the second iteration is starting. Also, the "new iteration" marker is moved to the end of the queue, so that pixels pushed subsequently will belong to iteration number 3.

ARGUMENTS

| Data type | Name | Description |
|----------------|--------------|--|
| dip_PixelQueue | queue | The queue structure |
| dip_int * | coords | Receives the coordinates of the popped item |
| void ** | pointer | Receives the pointer of the popped item |
| dip_Boolean * | newiteration | Set to true when the first item from an iteration is |
| | | popped |

SEE ALSO

 $\label{thm:pixelQueue} PixelQueueNew, PixelQueueFree, PixelQueuePush, PixelQueueIsEmpty$

PixelQueuePush

Push item onto queue

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueuePush ( queue, coords, pointer )
```

FUNCTION

Pushes a pixel onto the queue. See PixelQueueNew for information on the queue data structure. Both coords and pointer are stored, except if the stack was created with ndims set to 0, in which case the coords values are ignored.

coords is a pointer to an array of dip_ints, such as that obtained with
dip_IntegerArray->array. It should have as many elements as the image dimensionality.
pointer is a pointer to any memory location.

ARGUMENTS

| Data type | Name | Description |
|----------------|---------|--------------------------|
| dip_PixelQueue | queue | The queue structure |
| dip_int * | coords | Coordinates to be pushed |
| void * | pointer | Pointer to be pushed |

PixelTableAddRun

Add a new run to a pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableAddRun ( table, coordinate, length )
```

FUNCTION

Adds a new run to a pixel table. The new run is appended to the existing runs in the pixel table.

ARGUMENTS

| Data type | Name | Description |
|------------------|------------|-----------------------|
| dip_PixelTable | table | Pixel table |
| dip_IntegerArray | coordinate | Coordinate of the run |
| dip_int | length | Length of the run |

SEE ALSO

PixelTableCreateFilter

Create a pixel table from a filter shape

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableCreateFilter ( table, param, shape, se, resources )
```

FUNCTION

This function allocates and creates a new pixel table data structure. The shape and dimensionality of the pixel table is specified by the param, shape and se parameters.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|------------------|-----------|--|
| dip_PixelTable * | table | Pointer to a pixel table |
| dip_FloatArray | param | Filter size |
| dip_FilterShape | shape | Filter shape |
| dip_Image | se | Structuring element |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

PixelTableGetOffsetAndLength

Converts the pixel table's runs

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetOffsetAndLength ( table, stride, offset, length, resources )
```

FUNCTION

This functions converts the linked-list of runs in the pixel table to two arrays of offsets and lengths. The length of these arrays equals the number of runs. The offsets are calculated by multiplying each coordinate of a run with the stride of that dimension. This function is useful when an image needs to be filtered with a filter that is encoded by a pixel table. Before processing the image. See also PixelTableFrameWork.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_PixelTable | table | Pixel table |
| dip_IntegerArray | stride | Stride array |
| dip_IntegerArray * | offset | Pointer to offset array |
| dip_IntegerArray * | length | Pointer to length array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

Description of DIPlib's pixel tables

PixelTableGetOrigin

Get the origin of the pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetOrigin ( table, origin, resources )
```

FUNCTION

This function gets the origin of the pixel table table. All coordinates of the pixel table runs are defined relative to this origin. The origin is the pixel with coordinates (0,0), relative to the top left pixel.

Unless PixelTableShiftOrigin has been called, the origin is equal to the bounding box divided by 2 (integer divistion), meaning it is the middle pixel if the bounding box is odd in size, or the pixel to the right of the middle if it is even in size.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_PixelTable * | table | Pixel table |
| dip_IntegerArray * | origin | Pointer to a origin array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

PixelTableGetPixelCount

Get the number of pixels encoded in the pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetPixelCount ( table, count )
```

FUNCTION

Gets the total number of pixels of the binary object that is encoded by the Pixel table table.

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|------------------|
| dip_PixelTable | table | Pixel table |
| dip_int * | count | pointer to count |

PixelTableGetRun

607

Get the contents of a pixel table run

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetRun ( table, run, coordinate, length )
```

FUNCTION

This functions get the the coordinate and length parameters of the runth run of the pixel table table.

ARGUMENTS

| Data type | Name | Description |
|------------------|------------|---------------------------|
| dip_PixelTable | table | Pixel table |
| dip_int | run | The run to be initialised |
| dip_IntegerArray | coordinate | Coordinate of the run |
| dip_int * | length | Length of the run |

PixelTableGetRuns

Get the number of runs in a pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetRuns ( table, numberOfRuns )
```

FUNCTION

Gets the number of runs in a pixel table.

ARGUMENTS

| Data type | Name | Description |
|----------------|--------------|---------------------------|
| dip_PixelTable | table | Pixel table |
| dip_int * | numberOfRuns | Point to the NumberOfRuns |

PixelTableGetSize

609

The number of pixels in the pixel table's bounding box

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetSize ( table, size )
```

FUNCTION

Gets the number of pixels in the bounding box of the pixel table table.

ARGUMENTS

| Data type | Name | Description |
|----------------|-------|-----------------|
| dip_PixelTable | table | Pixel table |
| dip_int * | size | pointer to size |

SEE ALSO

Description of DIPlib's pixel tables

PixelTableNew

Allocate a new pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableNew ( table, size, runs, resource s)
```

FUNCTION

Allocates a new pixel table table. The size array specifies the dimensionality of the coordinates in each run, and the sizes of the bounding box of the pixel table. The runs parameter specifies the number of runs in the pixel table.

ARGUMENTS

| Data type | Name | Description |
|------------------|-----------|--|
| dip_PixelTable * | table | Pixel table |
| dip_IntegerArray | size | Size |
| dip_int | runs | Number of pixel table runs |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

PixelTableSetRun

Initialises a pixel table run

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableSetRun ( table, run, coordinate, length )
```

FUNCTION

This function initialises the runth run of the pixel table table, by setting the run's coordinate to coordinate and its length to length. The pixel table must at least consist of run number of runs and has to be allocated (using PixelTableNew).

ARGUMENTS

| Data type | Name | Description |
|------------------|------------|---------------------------|
| dip_PixelTable | table | Pixel table |
| dip_int | run | The run to be initialised |
| dip_IntegerArray | coordinate | Coordinate of the run |
| dip_int | length | Length of the run |

SEE ALSO

Description of DIPlib's pixel tables

PixelTableNew, PixelTableGetRun, PixelTableAddRun, PixelTableGetRuns, PixelTableGetDimensionality, PixelTableGetDimensions, PixelTableGetOrigin, PixelTableGetSize, PixelTableGetPixelCount, PixelTableGetOffsetAndLength

PixelTableShiftOrigin

Changes the origin of the pixel table

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableShiftOrigin ( table, offset )
```

FUNCTION

This function changes the origin of the pixel table table. By default, the origin is equal to the bounding box divided by 2 (integer divistion), meaning it is the middle pixel if the bounding box is odd in size, or the pixel to the right of the middle if it is even in size. After calling this function, the origin is equal to the previous origin plus the offset.

ARGUMENTS

| Data type | Name | Description |
|------------------|--------|--|
| dip_PixelTable | table | Pixel table |
| dip_IntegerArray | offset | An offset array, to be added to the origin |

SEE ALSO

Description of DIPlib's pixel tables

PixelTableToBinaryImage

Convert a pixel table to a binary image

SYNOPSIS

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableToBinaryImage ( table, im )
```

DATA TYPES

binary

FUNCTION

Converts the pixel table table to a binary image. The size of the image is set to the size of the bounding box of the pixel table.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------|-------|--------------|
| <pre>dip_PixelTable *</pre> | table | Pixel table |
| dip_Image | im | Binary image |

SEE ALSO

Description of DIPlib's pixel tables

BinaryImageToPixelTable, PixelTableCreateFilter

PoissonNoise

Generate an image disturbed by Poisson noise

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_PoissonNoise ( in, out, conversion, random )
```

DATA TYPES

integer, float

FUNCTION

Generate a Poisson noise disturbed image. The intensities of the input image divided by the conversion variable are used as mean value for the Poisson distribution. The conversion factor can be used to relate the pixel values with the number of counts. For example, the simulate a photon limited image acquired by a CCD camera, the conversion factor specifies the relation between the number of photons recorded and the pixel value it is represented by.

See PoissonRandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------------|--------------------------------|
| ${\tt dip_Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_float | conversion | Conversion factor (photon/ADU) |
| dip_Random * | random | random |

EXAMPLE

Get a Poisson disturbed image as follows:

```
dip_Image in, out;
dip_float conversion;
dip_Random random;

conversion = 2.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_PoissonNoise( in, out, conversion, &random ));
```

SEE ALSO

 $\label{thm:poissonRandomVariable} PoissonRandomVariable, RandomSeed, RandomSeedVector, \\ UniformNoise, GaussianNoise, BinaryNoise$

PoissonRandomVariable

Poisson random variable generator

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_PoissonRandomVariable ( random, mean, value )
```

FUNCTION

PoissonRandomVariable uses the algorithm as described in "Numerical Recipes in C, 2nd edition", section 7.3. For values of mean larger or equal to 32 the rejection method is used.

See RandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description | |
|--------------|--------|-------------------------------------|--|
| dip_Random * | random | Pointer to a random value structure | |
| dip_float | mean | Mean value for the distribution | |
| dip_float * | value | Poisson distributed output value | |

EXAMPLE

Get a Poisson random variable as follows:

```
dip_Random random;
dip_float mean, value;

mean = 23.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_PoissonRandomVariable( &random, mean, &value ));
```

ProbabilisticPairCorrelation

Compute the probabilistic pair correlation function

SYNOPSIS

#include "dip_analysis.h"
dip_Error dip_ProbabilisticPairCorrelation (phases, mask, dist, probes, length, sampling, covariance)

DATA TYPES

float

FUNCTION

This function computes the probabilistic pair correlation function of the different phases in phases. Each image in the image array phases is treated as a separate phase. The function assumes, but does not check, that the values in these images are with the [0 1] range. Optionally a mask image can be provided to select which pixels in object should be used to compute the pair correlation. The probes variable specifies how many random point pairs should be drawn to compute the function. Length specifies the maximum correlation length. The correlation function can be computed using a random

(DIP_CORRELATION_ESTIMATOR_RANDOM) or grid method

(DIP_CORRELATION_ESTIMATOR_GRID), as specified by sampling. Finally covariance determines whether only the correlations (DIP_FALSE) or the covarianances (DIP_TRUE) have to be computed.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|------------|----------------------|
| dip_ImageArray | phases | Phase image array |
| $	exttt{dip_Image}$ | mask | Mask image |
| dip_Distribution | dist | Ouput distribution |
| dip_int | probes | Number of probes |
| dip_int | length | Maximum chord length |
| dipf_CorrelationEstimator | sampling | Samplings method |
| dip_Boolean | covariance | Compute covariance |

SEE ALSO

PairCorrelation, ChordLength

PseudoInverse

Image restoration filter

SYNOPSIS

```
#include "dip_restoration.h"
dip_Error dip_PseudoInverse ( in, psf, out, threshold, flags )
```

FUNCTION

This function performs a basic, very noise sensitive image restoration operation by inverse filtering the image with a clipped point spread function. Each frequency in the output for which the response of the PSF is smaller than threshold is set to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|-----------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| dip_Image | psf | Point spread function image |
| dip_Image | out | Output image |
| dip_float | threshold | Threshold value |
| dipf_Restoration | flags | Restoration flags |

PutLine

Put a line in an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_PutLine ( in, out, cor, dimension )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Put a line in an image. Put a line orthogonally in an image. The position of the line in the image is specified by the coordinates at which its left most pixel (cor) is be placed and on which dimension of the image, the dimension of the line maps (dimension). If in has a different type than out, it will be converted to the type of out.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|---|
| dip_Image | in | Input Line Image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output Image |
| dip_IntegerArray | cor | Coordinate in the image of the left most pixel of the |
| | | line |
| dip_int | dimension | Dimension of the image on which the line's dimension |
| | | maps |

SEE ALSO

GetSlice, PutSlice, GetLine

PutSlice

Put a slice in an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_PutSlice ( in, out, cor, dim1, dim2 )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

Put a slice orthogonally in an image. The position of the slice in the image is specified by the coordinates at which its upper left corner (cor) should be placed and on which dimensions of the image, the dimensions of the slice map (dim1, dim2). If in has a different type than out, it will be converted to the type of out.

ARGUMENTS

| Data type | Name | Description | |
|------------------|------|---|--|
| dip_Image | in | 2D Input Image | |
| dip_Image | out | 3D Output Image | |
| dip_IntegerArray | cor | Coordinate in out where the upper left corner of in is | |
| | | placed | |
| dip_int | dim1 | Dimension of in on which the slice's first dimension maps | |
| dip_int | dim2 | Dimension of in on which the slice's second | |
| | | dimensionmaps | |

PutSlice, GetLine, PutLine

QuickSort

623

Sort a block of data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_QuickSort ( data, size, dataType )
```

FUNCTION

Sorts a block of data (of size size and data type dataType) using the quick sort algorithm.

ARGUMENTS

| Data type | Name | Description | |
|--------------|----------|------------------------------------|--|
| void * | data | Data | |
| dip_int | size | Size | |
| dip_DataType | dataType | Data type. See DIPlib's data types | |

QuickSortAnything

Sort data of any type

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_QuickSortAnything ( data, size, compareFunction, swapFunction,
tmpData )
```

FUNCTION

Sorts a block of data (of size size) using the quick sort algorithm. This routine requires the user to write two functions in order to fully implement the sorting procedure. These are SortCompareFunction and SortSwapFunction.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|-----------------|--|
| void * | data | Data |
| dip_int | size | Size |
| dip_SortCompareFunction | compareFunction | Function for comparing two data |
| | | points |
| dip_SortSwapFunction | swapFunction | Function for swapping two data points, |
| | | or copying one to the other |
| void * | tmpData | Pointer to a variable of the same type |
| | | as the data, used as temporary space |
| | | by some of the algorithms |

SEE ALSO

General information about sorting

SortAnything, SortCompareFunction, SortSwapFunction

QuickSortIndices

625

Sort indices to a block of data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_QuickSortIndices ( data, indices, size, dataType )
```

FUNCTION

Sort a list of indices rather than the data itself using the quick sort algorithm.

ARGUMENTS

| Data type | Name | Description |
|--------------|----------|------------------------------------|
| void * | data | Data |
| dip_sint32 * | indices | Indices |
| dip_int | size | Size |
| dip_DataType | dataType | Data type. See DIPlib's data types |

RadialMaximum

statistics function

SYNOPSIS

dip_Error dip_RadialMaximum (in, mask, out, ps, binSize, innerRadius, center
)

DATA TYPES

binary, integer, float

FUNCTION

This function computes the radial projection of the maximum of the pixel intensities of in. The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the maximum of the intensities of all pixels with n * binSize <= r < (n + 1) * binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP_TRUE, the maximum radius that is projected is equal to the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

ARGUMENTS

| Data type | Name | Description |
|------------------|-------------|------------------------------|
| $dip_{-}Image$ | in | Input |
| dip_Image | mask | Binary mask (or 0) |
| dip_Image | out | Output |
| dip_BooleanArray | ps | Dimensions to project (or 0) |
| dip_float | binSize | Size of radial bins |
| dip_Boolean | innerRadius | Maximum radius |
| dip_FloatArray | center | Coordinates of center (or 0) |

SEE ALSO

RadialSum, RadialMean, RadialMinimum, Sum, Mean, Maximum, Minimum

RadialMean

statistics function

SYNOPSIS

dip_Error dip_RadialMean (in, mask, out, ps, binSize, innerRadius, center)

DATA TYPES

binary, integer, float

FUNCTION

This function computes the radial projection of the mean of the pixel intensities of in.

The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the mean of the intensities of all pixels with n * binSize <= r < (n + 1) * binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP_TRUE, the maximum radius that is projected is equal to the the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $dip_{-}Image$ | mask | Binary mask (or 0) |
| dip_Image | out | Output |
| dip_BooleanArray | ps | Dimensions to project (or 0) |
| dip_float | binSize | Size of radial bins |
| dip_Boolean | innerRadius | Maximum radius |
| dip_FloatArray | center | Coordinates of center (or 0) |

SEE ALSO

RadialSum, RadialMaximum, RadialMinimum, Sum, Mean, Maximum, Minimum

RadialMinimum

statistics function

SYNOPSIS

dip_Error dip_RadialMinimum (in, mask, out, ps, binSize, innerRadius, center
)

DATA TYPES

binary, integer, float, complex

FUNCTION

This function computes the radial projection of the sum of the pixel intensities of in.

The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the minimum of the intensities of all pixels with n * binSize <= r < (n + 1) * binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP_TRUE, the maximum radius that is projected is equal to the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

ARGUMENTS

| Data type | Name | Description |
|------------------|-------------|------------------------------|
| dip_Image | in | Input |
| dip_Image | mask | Binary mask (or 0) |
| dip_Image | out | Output |
| dip_BooleanArray | ps | Dimensions to project (or 0) |
| dip_float | binSize | Size of radial bins |
| dip_Boolean | innerRadius | Maximum radius |
| dip_FloatArray | center | Coordinates of center (or 0) |

SEE ALSO

RadialSum, RadialMean, RadialMaximum, Sum, Mean, Maximum, Minimum

RadialSum

statistics function

SYNOPSIS

dip_Error dip_RadialSum (in, mask, out, ps, binSize, innerRadius, center)

DATA TYPES

binary, integer, float

FUNCTION

This function computes the radial projection of the sum of the pixel intensities of in.

The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the sum of the intensities of all pixels with n * binSize <= r < (n + 1) * binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP_TRUE, the maximum radius that is projected is equal to the the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| dip_Image | mask | Binary mask (or 0) |
| dip_Image | out | Output |
| dip_BooleanArray | ps | Dimensions to project (or 0) |
| dip_float | binSize | Size of radial bins |
| dip_Boolean | innerRadius | Maximum radius |
| dip_FloatArray | center | Coordinates of center (or 0) |

RadialMean, RadialMaximum, RadialMinimum, Sum, Mean, Maximum, Minimum

RandomSeed

Initialise random number generator

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_RandomSeed ( random, seed )
```

FUNCTION

Initializes a dip_Random structure using a given seed value. If seed is 0, the default value of 5489 is used instead, since 0 produces a uniquely poor initialisation.

ARGUMENTS

| Data type | Name | Description | |
|--------------|--------|-------------------------------------|--|
| dip_Random * | random | Pointer to a random value structure | |
| dip_uint32 | seed | Seed value | |

EXAMPLE

Initialize a dip_Random structure as follows:

```
dip_Random random;
dip_uint32 seed;
seed = 123758;
DIPXJ( dip_RandomSeed( &random, seed ));
```

SEE ALSO

RandomSeedVector

Initialise random number generator

SYNOPSIS

```
#include "dip_noise.h"
dip_Error RandomSeedVector ( random, seedvector )
```

FUNCTION

Initializes a dip_Random structure with a given seed value vector. The vector must have DIP_MT_STATE_SIZE (==624) values. This is an alternative to RandomSeed, which, by initialising with a 32-bit integer, only gives 4 billion different sequences. RandomSeedVector allows to initialise the whole status of the random number generator.

ARGUMENTS

| Data type | Name | Description |
|-------------------------------|------------|-------------------------------------|
| dip_Random * | random | Pointer to a random value structure |
| dip_uint32[DIP_MT_STATE_SIZE] | seedvector | Seed value vector |

SEE ALSO

RandomSeed, RandomVariable, UniformRandomVariable, GaussianRandomVariable, PoissonRandomVariable, BinaryRandomVariable

RandomVariable

Random number generator

SYNOPSIS

```
include "dip_noise.h"
dip_Error dip_RandomVariable ( random, value )
```

FUNCTION

Generates a random number between zero and one. The dip_Random structure must be initialized with the function RandomSeed. If the supplied dip_Random structure is not initialized, RandomVariable will initialize the dip_Random structure with the default seed. To guarantee the (psuedo) randomness between variables obtained with subsequent calls to RandomVariable (or to functions that use this function to obtain a random variable), a pointer to the same dip_Random structure has to supplied when calling RandomVariable.

The random number generator returns random numbers as 32-bit integers, which are normalised to to [0,1] range. If higher precision numbers are required, you can set random.highprecision to DIP_TRUE. This causes two random 32-bit values to be used for each floating point output value, doubling the precision of the output. There is no need to re-initialise the random structure after changing this setting.

This function is based on LGPL code by Geoff Kuenning (mtwist-0.8) implementing the Mersenne Twister pseudo-random number generator.

ARGUMENTS

| Data type | Name | Description | |
|--------------|--------|-------------------------------------|--|
| dip_Random * | random | Pointer to a random value structure | |
| dip_float * | value | Random value | |

EXAMPLE

Obtain a random number as follows:

```
dip_Random random;
dip_float val;

DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_RandomVariable( &random, &val ));
```

RangeThreshold

Point Operation

SYNOPSIS

#include "dip_point.h"
dip_Error dip_RangeThreshold (in, out, lowerBound, upperBound, foreground, background, binaryOutput)

DATA TYPES

integer, float

FUNCTION

out = (lowerBound <= in <= upperBound? foreground: background) If the boolean binaryOutput is true, RangeThreshold will produce a binary image. Otherwise an image of the same type as the input image is produced, with the pixels set to either foreground or background.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|--------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_float | lowerBound | Lower bound |
| $	ext{dip_float}$ | upperBound | Upper bound |
| dip_float | foreground | Foreground value |
| $\mathtt{dip}_{-}\mathtt{float}$ | background | Background value |
| dip_Boolean | binaryOutput | Convert output image to binary |

SEE ALSO

Threshold, HysteresisThreshold, IsodataThreshold

Real

Arithmetic function

SYNOPSIS

dip_Error dip_Real (in, out)

DATA TYPES

binary, integer, float, complex

FUNCTION

Computes the real part of the input image values, and outputs a float typed image.

ARGUMENTS

| Data type | Name | Description |
|--------------------|------|-------------|
| ${\tt dip_Image}$ | in | Input |
| dip_Image | out | Output |

SEE ALSO

Modulus, Phase, Imaginary

Reciprocal

arithmetic function

SYNOPSIS

dip_Error dip_Reciprocal (in, out)

DATA TYPES

binary, integer, float, complex

FUNCTION

Computes the reciprocal (1/x) of the input image values. If pixel values of in are zero, the corresponding pixels in out is set to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |

Register

Generic registry function

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_Register ( register )
```

FUNCTION

The Registry functions Register, Unregister, RegisterClass, RegistryList, RegistryGet RegistryValid and RegistryArrayNew are the access functions for DIPlib's generic registry framework. These functions control the access to a registry containing information of items that are registered at run-time. Each item belongs to a certain class and is identified with an ID that is unique within the item's class.

DIPlib's Registry classes are registered at run-time as well (using RegisterClass) and should be registered before an item of that class can registered.

Although the generic Registry functions can be used to register, and obtain the data of registered items of a specific clas, it is more user friendly to use class-specific Registry functions like MeasurementFeatureRegister and companions.

The dip_Register function accepts one argument, a dip_Registry structure, which contains the ID and class of the to be registered data and registry, a pointer to class-specific data. Note that this pointer, registry, is freed when the (global) registry information is freed.

The following code gives an example of a class-specific register function:

```
dip_Error dip_MeasurementFeatureRegister
(
    dip_MeasurementFeatureRegistry registry
)
{
    DIP_FN_DECLARE("dip_MeasurementFeatureRegister");
    dip_Registry globalRegistry;
    void *data;
    dip_MeasurementFeatureRegistry *reg;

    switch( registry.type )
    {
        default:
            DIPSJ( DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
            break;
```

```
case DIP_MSR_FUNCTION_LINE_BASED:
      DIPTS( ! ( registry.create &&
           registry.measure.line &&
           registry.value &&
           registry.labels &&
           registry.description),
       DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
      break;
   case DIP_MSR_FUNCTION_IMAGE_BASED:
      DIPTS(! (registry.create &&
           registry.measure.image &&
           registry.value &&
           registry.labels &&
           registry.description),
       DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
      break;
   case DIP_MSR_FUNCTION_CHAINCODE_BASED:
      DIPTS( ! ( registry.create &&
           registry.measure.chaincode &&
           registry.value &&
           registry.labels &&
           registry.description),
      DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
      break;
   case DIP_MSR_FUNCTION_COMPOSITE:
      DIPTS( ! ( registry.create &&
           registry.measure.composite &&
           registry.value &&
           registry.convert &&
           registry.description),
      DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
      break;
/* copy the Measurement specific registry info */
DIPXJ( dip_MemoryNew( &data, sizeof( dip_MeasurementFeatureRegistry ), 0 ));
reg = ( dip_MeasurementFeatureRegistry * ) data;
*reg = registry;
globalRegistry.id
                        = registry.id.rtid;
                        = DIP_REGISTRY_CLASS_MEASUREMENT;
globalRegistry.class
globalRegistry.registry = reg;
globalRegistry.free
                       = dip_MemoryFree;
```

```
/* register this measurement registry data */
   DIPXJ( dip_Register( globalRegistry ));
dip_error:
   DIP_FN_EXIT;
}
```

ARGUMENTS

| Data type | Name | Description | |
|--------------|----------|----------------------------|--|
| dip_Registry | registry | Generic registry structure | |

SEE ALSO

 $\label{thm:continuous} \begin{tabular}{ll} Unregister, RegisterClass, RegistryList, RegistryGet, RegistryValid, RegistryArrayNew \end{tabular}$

RegisterClass

Register a registry class

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_RegisterClass ( class )
```

FUNCTION

This function registers a Registry class. See Register for more information about DIPlib's Registry.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|-------|-------------------|
| $\mathtt{dip}_{-}\mathtt{int}$ | class | Registry class ID |

SEE ALSO

Register, Unregister, RegistryValid, RegistryList, RegistryGet, RegistryArrayNew

RegistryArrayNew

Allocate a registry array

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_RegistryArrayNew ( array, size, resources )
```

FUNCTION

This function allocates an array of dip_Registry structures.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-----------|--|
| dip_RegistryArray * | array | Pointer to the allocated array |
| dip_int | size | Array size |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

Register, RegistryList, RegistryGet

643

RegistryGet

Get a registry item

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_RegistryGet ( id, class, registry )
```

FUNCTION

This function obtains the Registry information of the ID of the Registry class class. See Register for more information about DIPlib's Registry.

The following code gives an example of a class-specific register list function:

```
dip_Error dip_MsrRegistryGet
(
    dip_int id,
    dip_MsrRegistry *registry
)
{
    DIP_FN_DECLARE("dip_MsrRegistryGet");
    dip_MsrRegistry *reg;
    void *data;

    DIPXJ( dip_RegistryGet ( id, DIP_REGISTRY_CLASS_MEASUREMENT, &data ));
    reg = data;
    *registry = *reg;

dip_error:
    DIP_FN_EXIT;
}
```

ARGUMENTS

| Data type | Name | Description | |
|---|----------|----------------------------|--|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{int}$ | id | Registry ID | |
| dip_int | class | Registry class | |
| dip_void ** | registry | Pointer to registered data | |

SEE ALSO

RegistryList

645

Get an array of registry IDs

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_RegistryList ( id, class, resources )
```

FUNCTION

This function obtains an array of the registered IDs of the Registry class class. See Register for more information about DIPlib's Registry.

The following code gives an example of a class-specific register list function:

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_IntegerArray * | id | Pointer to an array of Registry IDs |
| dip_int | class | Registry class |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

Register, Unregister, RegisterClass, RegistryGet, RegistryValid, RegistryArrayNew

RegistryValid

Validate an registry item

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_RegistryValid ( id, class, verdict )
```

FUNCTION

This function checks whether id has been registered in the Registry in the Registry class class. If verdict is not zero, the validation information (DIP_FALSE or DIP_TRUE) is copied to verdict. Otherwise an error is returned in case the validation fails.

See Register for more information about DIPlib's Registry.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|---------|---|
| $\mathtt{dip}_{-}\mathtt{int}$ | id | Registry ID |
| $\mathtt{dip}_{-}\mathtt{int}$ | class | Registry class |
| dip_Boolean * | verdict | Pointer to a boolean containing the validation data |

SEE ALSO

Register, Unregister, RegisterClass, RegistryList, RegistryGet, RegistryArrayNew

Resampling

Interpolation function

SYNOPSIS

```
#include "dip_interpolation.h"
dip_Error dip_Resampling ( in, out, zoom, shift, method )
```

DATA TYPES

binary, integer, float

FUNCTION

This function resmaples the input image in to out using various interpolation methods. Both a (subpixel) shift and a zoom factor are supported. The size of the output image is zoom times the size of in. If shift is zero, a shift of zero is assumed. If zoom is zero, a zoom of 1.0 is assumed.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------|----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_FloatArray | zoom | Zoom factor |
| dip_FloatArray | shift | Shift |
| dipf_Interpolation met | | Interpolation method |

The dipf_Interpolation enumaration consists of the following constants:

| Name | Description |
|--------------------------------------|---------------------------------|
| DIP_INTERPOLATION_DEFAULT | Default interpolation method |
| DIP_INTERPOLATION_BSPLINE | B-Spline interpolation |
| DIP_INTERPOLATION_FOURTH_ORDER_CUBIC | Forth order cubic interpolation |
| DIP_INTERPOLATION_THIRD_ORDER_CUBIC | Third order cubic interpolation |
| DIP_INTERPOLATION_LINEAR | Linear interpolation |
| DIP_INTERPOLATION_ZERO_ORDER_HOLD | Zero order hold interpolation |

SEE ALSO

Subsampling

ResourcesFree

Free resources

SYNOPSIS

dip_Error dip_ResourcesFree(resources, flags)

FUNCTION

Free all resources registers in the resource tracking structure, as well as the resource tracking structure itself. To prevent errors, the resource tracking structure is set to 0. Passing a null pointer instead of a pointer to a dip_Resources structure is allowed and silently ignored.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|---|
| dip_Resources * | resources | The tracking structure which was used to register |
| | | the resources that must be freed. Note the double |
| | | pointer, allowing this routine to set your pointer to 0 |
| dipf_ResourcesFree | flags | When set to DIP_RMRF_DONT_FREE, |
| | | dip_ResourcesFree only frees the dip_Resources |
| | | structure itself, not the resources associated with it |

SEE ALSO

 ${\tt ResourceSNew,\,ResourceSMerge,\,ResourceSubscribe,\,ResourceUnsubscribe}$

ResourcesMerge

Add one resource list to another

SYNOPSIS

dip_Error dip_ResourcesMerge(resources, mergee)

FUNCTION

Adds one resource list to another. This function is very useful when writing functions that will support a dip_Resources parameter. Typically you want to allocate a number of resources and only add these to the user-supplied dip_Resources when all these allocations have been successful. This is where ResourcesMerge comes in. Allocate a local dip_Resources structure and register all resources with it. When no errors occured the local dip_Resources structure can be merged with the user-supplied dip_Resources structure. If an error did occur, simply free all local resources by calling ResourcesFree. In addition it is the convention that functions supporting resource tracking also accept a zero indicating that no tracking should be performed. When resources in dip_ResourcesMerge is 0, the mergee tracking structure is freed, but the resources it contains are not. In this way you get support for the "resources = 0 means no tracking" convention for free.

ARGUMENTS

| Data type | Name | Description | |
|-----------------|-----------|---|--|
| dip_Resources | resources | The dip_Resources structure with which the additional | |
| | | resources much be merged | |
| dip_Resources * | mergee | A pointer to the dip_Resources structure containing | |
| | | the additional resources to be merged. After the merge, | |
| | | mergee is set to 0. | |

SEE ALSO

ResourcesNew, ResourcesFree, ResourceSubscribe, ResourceUnsubscribe

ResourcesNew

Allocate a resource tracking structure

SYNOPSIS

dip_Error dip_ResourcesNew(resources, noItems)

FUNCTION

This function allocates a dip_Resources structure. The resource structure can be used to register various resources as they are allocated, provided that the allocating function allows you to register the resource. All resources allocated in this manner can be freed with a single call to ResourcesFree. Examples of functions supporting this registration scheme are ImageNew and special versions of the memory allocation routines.

Some operations consist of an initialization and a cleanup stage. These stages are often performed by separate routines to allow the user to execute his/her own operations in between. In DIPlib there usually is no directly callable cleanup function. Instead the initialization routine registers its cleanup routine with a dip_Resources structure provided by the user. The cleanup operation is invoked through ResourcesFree.

All functions that support the registration leave you the choice not to register the resource. This is indicated by supplying a zero instead of a resource tracking structure, unless documented otherwise. The noItems parameters can be used to give the routine a hint about the number of resources you will register. The structure grows automagically whenever more resources are registered than indicated by the hint parameter.

ARGUMENTS

| Data type | Name | Description | |
|-----------------|-----------|--|--|
| dip_Resources * | resources | This will be used to return a dip_Resources structure | |
| dip_int | noItems | A hint about the number of resources you are planning | |
| | | to allocate. This parameter must be ≥ 2 or 0 to | |
| | | indicate you want the default value. By the way, don't | |
| | | worry too much about this parameter, because when | |
| | | the structure turns out to be too small, it will | |
| | | automatically be expanded | |

SEE ALSO

ResourceSubscribe

Track a resource

SYNOPSIS

dip_Error dip_ResourceSubscribe(resource, freeResourceHandler, resources)

FUNCTION

Track a resource. The resource must be represented by a void *. A handler function to free the resource must be given. This function will be called through dip_ResourcesFree with the resource as its only parameter. If dip_ResourceSubscribe fails, the resource is not registered. It is allowed to pass a zero instead of a dip_Resources structure, in which case dip_ResourceSubscribe returns silently.

ARGUMENTS

| Data type | Name | Description |
|--------------------------|---------------------|-----------------------------------|
| void * | resource | The resource that must be |
| | | registered |
| dip_ResourcesFreeHandler | freeResourceHandler | The handler function that will be |
| | | invoked by dip_ResourcesFree |
| | | to free the resource |
| dip_Resources | resources | dip_Resources structure to |
| | | register the resource with |

SEE ALSO

ResourcesNew, ResourcesFree, ResourcesMerge, ResourceUnsubscribe

ResourceUnsubscribe

Stop tracking a resource

SYNOPSIS

dip_Error dip_ResourceUnsubscribe(resource, resources)

FUNCTION

Stop tracking a resource. It will be removed from the dip_Resources structure. The resource itself will not be freed. If a zero is passed instead of a resource or the dip_Resources structure, dip_ResourceUnsubscribe returns silently.

ARGUMENTS

| Data type | Name | Description | |
|---------------|-----------|---|--|
| void * | resource | The resource that should no longer be tracked | |
| dip_Resources | resources | dip_Resources structure to remove the resource from | |

ResourcesNew, ResourcesFree, ResourcesMerge, ResourceSubscribe

${\tt RootMeanSquareError}$

difference measure

SYNOPSIS

dip_Error dip_RootMeanSquareError (in1, in2, mask, out)

DATA TYPES

binary, integer, float, complex

FUNCTION

Calculates the root mean square difference between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|--------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| dip_Image | mask | Mask |
| dip_Image | out | Output |

SEE ALSO

MeanError, MeanSquareError, MeanAbsoluteError, LnNormError, IDivergence

Rotation

Interpolation function

SYNOPSIS

```
#include "dip_interpolation.h"
dip_Error dip_Rotation ( in, out, angle, method, bgval )
```

DATA TYPES

binary, integer, float

FUNCTION

This function rotates an 2-D image in over angle to out using three skews. The function implements the rotation in the mathmetical sense, **but** note the Y-axis is positive downwards! The rotation is over the centre of the image.

ARGUMENTS

| Data type | Name | Description |
|----------------------|-----------------|----------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_float | angle (radians) | Rotation angle |
| $dipf_Interpolation$ | method | Interpolation method |
| dip_BackgroundValue | bgval | Background value |

The ${\tt dipf_Interpolation}$ enumaration consists of the following constants:

| Name | Description |
|--------------------------------------|---------------------------------|
| DIP_INTERPOLATION_DEFAULT | Default interpolation method |
| DIP_INTERPOLATION_BSPLINE | B-Spline interpolation |
| DIP_INTERPOLATION_FOURTH_ORDER_CUBIC | Forth order cubic interpolation |
| DIP_INTERPOLATION_THIRD_ORDER_CUBIC | Third order cubic interpolation |
| DIP_INTERPOLATION_LINEAR | Linear interpolation |
| DIP_INTERPOLATION_ZERO_ORDER_HOLD | Zero order hold interpolation |

The dip_BackgroundValue enumaration consists of the following flags:

| Name | Description | |
|-------------------|---------------------------------------|--|
| DIP_BGV_DEFAULT | Default: fill with zeros | |
| DIP_BGV_ZERO | Fill with zeros | |
| DIP_BGV_MAX_VALUE | Fill with maximum value for data type | |
| DIP_BGV_MIN_VALUE | Fill with minimum value for data type | |

KNOWN BUGS

This function is only implemented for 2D images.

SEE ALSO

Skewing

Rotation3d

Interpolation function

SYNOPSIS

```
#include "dip_interpolation.h"
dip_Error dip_Rotation3d ( in, out, alpha, beta, gamma, method, bgval )
```

DATA TYPES

binary, integer, float

FUNCTION

This function rotates an 3-D image in via the three Euler angles alpha, beta, gamma to out using nine skews. The first rotation is about alpha around the initial 3-axis. The second about beta around the intermediate 2-axis and the last about gamma around the final 3-axis. The function implements the rotation in the mathmetical sense, but note the Y-axis is positive downwards! The rotation is over the centre of the image.

ARGUMENTS

| Data type | Name | Description |
|---|-----------------|----------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_float | alpha (radians) | Euler angle |
| dip_float | beta (radians) | Euler angle |
| dip_float | gamma (radians) | Euler angle |
| $\mathtt{dipf}_{-}\mathtt{Interpolation}$ | method | Interpolation method |
| dip_BackgroundValue | bgval | Background value |

The dipf_Interpolation enumaration consists of the following constants:

| Name | Description |
|--------------------------------------|---------------------------------|
| DIP_INTERPOLATION_DEFAULT | Default interpolation method |
| DIP_INTERPOLATION_BSPLINE | B-Spline interpolation |
| DIP_INTERPOLATION_FOURTH_ORDER_CUBIC | Forth order cubic interpolation |
| DIP_INTERPOLATION_THIRD_ORDER_CUBIC | Third order cubic interpolation |
| DIP_INTERPOLATION_LINEAR | Linear interpolation |
| DIP_INTERPOLATION_ZERO_ORDER_HOLD | Zero order hold interpolation |

The dip_BackgroundValue enumaration consists of the following flags:

| Name | Description | |
|-------------------|---------------------------------------|--|
| DIP_BGV_DEFAULT | Default: fill with zeros | |
| DIP_BGV_ZERO | Fill with zeros | |
| DIP_BGV_MAX_VALUE | Fill with maximum value for data type | |
| DIP_BGV_MIN_VALUE | Fill with minimum value for data type | |

KNOWN BUGS

This function is only implemented for 3D images.

SEE ALSO

Skewing, Rotation3d_Axis

Rotation3d Axis

Interpolation function

SYNOPSIS

```
#include "dip_interpolation.h"
dip_Error dip_Rotation3d_Axis ( in, out, angle, axis, method, bgval )
```

DATA TYPES

binary, integer, float

FUNCTION

This function rotates an 3-D image in over angle around axis to out using three skews. The rotation axis is 0(x), 1(y) or 2(z). The function implements the rotation in the mathmetical sense, but note the Y-axis is positive downwards! The rotation is over the centre of the image.

For backwards compatability, the macro Rotation3dAxis calls the function Rotation3dAxis but uses 1, 2 and 3 to select the axis of rotation.

ARGUMENTS

| Data type | Name | Description |
|--|-----------------|----------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_float | angle (radians) | Rotation angle |
| dip_int | axis | Rotation axis |
| $\mathtt{dipf}_{\mathtt{-}}\mathtt{Interpolation}$ | method | Interpolation method |
| dip_BackgroundValue | bgval | Background value |

The dipf_Interpolation enumaration consists of the following constants:

| Name | Description |
|--------------------------------------|---------------------------------|
| DIP_INTERPOLATION_DEFAULT | Default interpolation method |
| DIP_INTERPOLATION_BSPLINE | B-Spline interpolation |
| DIP_INTERPOLATION_FOURTH_ORDER_CUBIC | Forth order cubic interpolation |
| DIP_INTERPOLATION_THIRD_ORDER_CUBIC | Third order cubic interpolation |
| DIP_INTERPOLATION_LINEAR | Linear interpolation |
| DIP_INTERPOLATION_ZERO_ORDER_HOLD | Zero order hold interpolation |

The dip_BackgroundValue enumaration consists of the following flags:

| Name | Description |
|-------------------|---------------------------------------|
| DIP_BGV_DEFAULT | Default: fill with zeros |
| DIP_BGV_ZERO | Fill with zeros |
| DIP_BGV_MAX_VALUE | Fill with maximum value for data type |
| DIP_BGV_MIN_VALUE | Fill with minimum value for data type |

KNOWN BUGS

This function is only implemented for 3D images.

ScanFrameWork

FrameWork for scanning multiple images

SYNOPSIS

 $\label{lem:conformed} $$ \dim_{\mathbb{Z}}$ CanFrameWork (in, out, process, boundary, border, inBuffer, outBuffer, outImage)$

FUNCTION

This function provides a framework for scanning nofin input images and nofout output images in one dimension of the images. The dimension in which the image should be scanned can be specified or left to ScanFrameWork by specifying the dimension with DIP_MONADIC_OPTIMAL_DIMENSION. See SeparableFrameWork for details.

ARGUMENTS

| Data type | Name | Description |
|---|-----------|---|
| $\mathtt{dip}_{-}ImageArray$ | in | Array of input images |
| $\mathtt{dip}_{	extsf{-}}\mathtt{ImageArray}$ | out | Array of output images |
| dip_FrameWorkProcess | process | Process |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BorderArray | border | Border Array |
| dip_DataTypeArray | inBuffer | Array of dip_DataType of the input buffer |
| dip_DataTypeArray | outBuffer | Array of dip_DataType of each output buffer |
| dip_DataTypeArray | outImage | Array of dip_DataType of each output image |

SeededWatershed

Morphological segmentation

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_SeededWatershed ( seeds, in, mask, out, connectivity, order,
max_depth, max_size, binaryOutput )
```

DATA TYPES

integer, float

FUNCTION

Watershed segmentation with built-in region merging. max_depth and max_size control the merging procedure. Any region with max_size or less pixels and with max_depth grey-value difference or less will be merged to neighbouring regions when they touch (as opposed to build a watershed). max_size equal to 0 means that the size of the region is not tested when merging. To avoid merging of seeds with no grey-value difference between them, set max_size to a negative value. The regions are grown according to the connectivity parameter. See The connectivity parameter for more information. The output is either a labelled image where the pixels belonging to a catchment basin are labelled, or a binary image where the watershed pixels are 1 and the rest is 0. This is controlled by binaryOutput.

As opposed to Watershed, this function takes a seeds input image, and grows the catchment basins from there. The output image, when binaryOutput is DIP_TRUE, will have label values as given by the seed image.

If mask is not 0, only the pixels within mask will be considered. All the other pixels will be untouched.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|--------------|--|
| dip_Image | seeds | Binary or labelled input image |
| dip_Image | in | Grey-value input image |
| dip_Image | mask | Mask image |
| ${\tt dip_Image}$ | out | Output |
| dip_int | connectivity | Connectivity |
| dipf_GreyValueSortOrder | order | Whether to grow from low to high or high |
| | | to low |
| dip_float | max_depth | Maximum depth of a region that can be |
| | | merged |
| dip_int | max_size | Maximum size of a region that can be |
| | | merged |
| dip_Boolean | binaryOutput | DIP_FALSE if the output should be a |
| | | labelled image |

The ${\tt dipf_GreyValueSortOrder}$ enumeration consists of the following values:

| Name | Description |
|---------------------|--|
| DIP_GVSO_HIGH_FIRST | Process the pixels from high grey-value to low grey-value. |
| DIP_GVSO_LOW_FIRST | Process the pixels from low grey-value to high grey-value. |

Select

Configurable selection function

SYNOPSIS

dip_Error dip_Select (in1, in2, in3, in4, out, selector)

DATA TYPES

binary, integer, float

FUNCTION

This function can perform various pixel-by-pixel comparisons (smaller, smaller- equal, equal, not equal, greater-equal, greater) between in1 ans in2. If the result of the comparison is true, the corresponding pixel value of in3 is copied to out, otherwise it is copied from in4. In short the following operation is performed for each pixel in the five images:

```
out = in1 selector in2 ? in3 : in4
```

The images in 2, in 3 and in 4 can be 0-D images acting as constants.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|------------------------|
| dip_Image | in1 | First input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in3 | Third input |
| dip_Image | in4 | Fourth input |
| dip_Image | out | Output |
| dipf_Select | selector | Select flag |
| Name | | Description |
| DIP_SELECT_L | ESSER | <, Lesser than |
| DIP_SELECT_LESSER_EQUAL | | <=, Lesser or equal |
| DIP_SELECT_NOT_EQUAL | | !=, Unequal |
| DIP_SELECT_EQUAL | | ==, Equal |
| DIP_SELECT_GREATER_EQUAL | | L >=, Greater or equal |
| DIP_SELECT_GREATER | | >, Greater |

SeparableConvolution

667

FrameWork for separable convolution filters

SYNOPSIS

#include "dip_linear.h"
dip_Error dip_SeparableConvolution (in, out, filters, bc, process)

DATA TYPES

integer, float

FUNCTION

This function is a frontend to the lower level Convolve1d function. Each dimension can be processed by a different filter.

process may be zero, indicating that all dimensions should be processed.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|-----------------------|
| ${\tt dip_Image}$ | in | Input image |
| dip_Image | out | Output image |
| dip_SeparableConvolutionFilter * | filters | Filters |
| dip_BoundaryArray | bc | Boundary conditions |
| dip_BooleanArray | process (0) | Dimensions to process |

The ${\tt dip_SeparableConvolutionFilter}$ structure contains the following elements:

| Data type | Name | Description |
|---------------|------------|--|
| dip_float * | filter | Filter weights |
| dip_int | filterSize | Length of filter array |
| dip_int | origin | Origin of the filter, only valid in conjunction with |
| | | DIP_CNV_USE_ORIGIN |
| dipf_Convolve | flags | Filter flags, see Convolve1d for their definitions |

FrameWork for separable filters

SYNOPSIS

dip_Error dip_SeparableFrameWork (in, out, boundary, border, process)

FUNCTION

The dip_SeparableFrameWork function is a framework for separable filters. This function takes care of all the "administrative work" involved when processing a n-D DIPlib image n times with a 1-D filter. In short, using this function, one has only to create an one dimension filter function and dip_SeparableFrameWork takes care of the other stuff. The in image is filtered nrOfProcesses times using the information in each element of the process array. If nrOfProcesses is zero, only the first element of process is used to filter in in all its dimensions.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|----------|--|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_IntegerArray | border | Border array |
| dip_FrameWorkProcessArray | process | Array of dip_FrameWorkProcess structures |

NOTE

The dip_FrameWorkProcess structure contains the following members:

| Data type | Name | Description |
|-------------------------|---------------------|------------------------------------|
| dip_Boolean | process | flags specifying to do processing |
| | | or not |
| dipf_FrameWorkMethod | frameWorkMethod | flags specifying the method of how |
| | | dip_SeparableFrameWork should |
| | | transport data from in to out |
| dipf_FrameWorkOperation | frameWorkOperation | flags specifying requirements of |
| | | the 1-D filter function |
| dip_int | processDimension | dimension of in to be processed |
| dip_int | roiOrigin | ignored in current implementation |
| dip_int | roiSize | ignored in current implementation |
| dipf_FrameWorkFilter | FrameWorkFilterType | specifying the type of 1-D filter |
| | | function |
| dip_FrameWorkFilter | FrameWorkFilter | pointer to the 1-D filter function |
| void * | functionParameters | parameters of the 1-D filter |
| | | function, for all dimensions |
| dip_DataType | inputBufferType | data type of input buffer |
| dip_DataType | outputBufferType | data type of output buffer |
| dip_DataType | suggestedOutputType | data type of output image |

The ${\tt dipf_FrameWorkMethod}$ enum contains the following elements:

| Name | Description |
|------------------------------|---|
| DIP_FRAMEWORK_DEFAULT_METHOD | use dip_SeparableFrameWorks most optimal method |
| DIP_FRAMEWORK_CLASSICAL | use a classical method |
| DIP_FRAMEWORK_DOUBLE_STRIPE | use two buffers to store temporary results |

It is strongly advised to use the ${\tt DIP_FRAEMWORK_DEFAULT_METHOD}$ method.

The ${\tt dipf_FrameWorkOperation}$ enum contains the following elements:

| Name | Description | |
|---------------------------------|--|--|
| DIP_FRAMEWORK_DEFAULT_OPERATION | default operation | |
| DIP_FRAMEWORK_IN_PLACE | filtering operation can be performed in-place. It is | |
| | up to dip_SeparableFrameWork whether the | |
| | actual filtering is done in-place | |
| DIP_FRAMEWORK_NO_IN_BORDER | the 1-D filter does not need border extension of | |
| | the input data | |
| DIP_FRAMEWORK_OUT_BORDER | the 1-D filter needs border extension of the output | |
| | data | |
| DIP_FRAMEWORK_WRITE_INPUT | the 1-D filter needs to write in the input data | |
| DIP_FRAMEWORK_USE_BUFFER_TYPES | made the input and output buffers of the | |
| | inputBufferType and outputBufferType data | |
| | type | |
| DIP_FRAMEWORK_NO_BUFFER_STRIDE | Create input and outpub buffers with a stride of | |
| | one | |
| DIP_FRAMEWORK_DO_NOT_ADJUST | Do not adjust the output image, just check it | |
| DIP_FRAMEWORK_USE_OUTPUT_TYPE | Adjust output image to the suggestedOutputType | |
| | data type | |

| The dipf_FrameWorkFilter enum | n contains the following | elements: |
|-------------------------------|--------------------------|-----------|
|-------------------------------|--------------------------|-----------|

| Name | Description |
|--|--|
| DIP_FRAMEWORK_SEPARABLE_FILTER | default filter type, process one line at |
| | the time |
| DIP_FRAMEWORK_TWO_LINES_SEPARABLE_FILTER | process two lines in one go |
| DIP_FRAMEWORK_SINGLE_OUTPUT_FILTER | this filter only needs an output buffer |

The union dip_FrameWorkFunction consists of the types

| Name | Description |
|-------------------------------------|----------------------------|
| dip_SeparableFilter | one line filter function |
| ${	t dip_TwoLinesSeparableFilter}$ | two lines filter function |
| dip_SingleOutputFilter | single output image filter |

The functions have the following arguments: dip_SeparableFilter

| Data type | Name | Description |
|-------------------------------|----------|--------------------------------------|
| void * | inData | pointer to the input data |
| void * | outData | pointer to the output data |
| dip_int | elements | number of pixels in the inData array |
| dip_SeparableFilterParameters | params | parameter structure for the filter |
| | | function |

and ${\tt dip_SeparableTwoLinesFilter}$

| Data type | Name | Description |
|---------------------------------------|-------------------|---------------------|
| void * | inFirstLineData | pointer to the data |
| | | of the first input |
| | | line |
| void * | inSecondLineData | pointer to the data |
| | | of the second input |
| | | line |
| void * | outFirstLineData | pointer to the data |
| | | of the first output |
| | | line |
| void * | outSecondLineData | pointer to the data |
| | | of the second |
| | | output line |
| dip_int | elements | number of pixels in |
| | | the |
| | | inFirstLineData |
| | | array |
| dip_TwoLinesSeparableFilterParameters | params | parameter structure |
| | | for the two lines |
| | | filter function |

The inData, inFirstLineData and inSecondLineData will always point to the first pixel of the line of in that is processed. Therefore, the 1-D filter can access pixels with indices ranging from -border[dimension] up to elements + border[dimension]. If the flag DIP_FRAMEWORK_OUT_BOUNDARY is specified, the same holds for the output data pointers.

671

| Data type | Name | Description |
|------------------|--------------------|---|
| void * | functionParameters | parameters of the 1-D filter function per |
| | | dimension |
| dip_int | dimension | the dimension in which direction the input |
| | | buffer is taken from the input image |
| dip_int | processNumber | number of times dip_SeparableFrameWork |
| | | has already filtered in with an 1-D filter |
| | | including current filtering |
| dip_DataType | inType | dip_DataType of the input buffer |
| dip_int | inStride | stride of the elements in the input array |
| dip_int | inPlane | plane number in case in is a binary image |
| dip_DataType | outType | dip_DataType of the output buffer |
| dip_int | outStride | stride of the elements in the output array |
| dip_int | outPlane | plane number in case out is a binary image |
| dip_int | outDimension | the dimension in which direction the output |
| | | buffer is taken from the output image |
| dip_IntegerArray | position | coordinate of the first pixel of the input |
| | | buffer in the input image |

The structure $\mathtt{dip_TwoLinesSeparableFilterParameters}$ contains the following elements:

| Data type | Name | Description |
|------------------|--------------------|---|
| void * | functionParameters | parameters of the 1-D filter function per |
| | | dimension |
| dip_int | dimension | the dimension in which direction the input |
| | | buffer is taken from the input image |
| dip_int | processNumber | number of times dip_SeparableFrameWork |
| | | has already filtered in with an 1-D filter |
| | | including current filtering |
| dip_DataType | inType | dip_DataType of the input buffer |
| dip_int | inStride | stride of the elements in the input array |
| dip_int | inPlane | plane number in case in is a binary image |
| dip_DataType | outType | dip_DataType of the output buffer |
| dip_int | outStride | stride of the elements in the output array |
| dip_int | outPlane | plane number in case out is a binary image |
| dip_int | outDimension | the dimension in which direction the output |
| | | buffer is taken from the output image |
| dip_IntegerArray | position | coordinate of the first pixel of the input |
| | | buffer in the input image |

The structure $\mathtt{dip_SingleOutputFilterParameters}$ contains the following elements:

| Data type | Name | Description |
|------------------|--------------------|--|
| void * | functionParameters | parameters of the 1-D filter function per |
| | | dimension |
| dip_int | dimension | the dimension in which direction the input |
| | | buffer is taken from the input image |
| dip_int | processNumber | number of times dip_SeparableFrameWork |
| | | has already filtered in with an 1-D filter |
| | | including current filtering |
| dip_DataType | type | dip_DataType of the input buffer |
| dip_int | stride | stride of the elements in the input array |
| dip_int | plane | plane number in case in is a binary image |
| dip_IntegerArray | position | coordinate of the first pixel of the input |
| | | buffer in the input image |

Set

the value of a pixel

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Set ( out, const, cor, adjust )
```

FUNCTION

This function set a value of a pixel at position cor in the image out to the value const.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------------|----------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | constImage | 0-D image |
| dip_IntegerArray | cor | Pixel coordinate |
| dip_Boolean | adjust | Adjust data type of output image |

SEE ALSO

SetInteger, SetFloat, SetComplex, dip_PixelSetInteger, dip_PixelSetFloat, Get

SetComplex

Set a pixel value

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_SetComplex ( out, constant, cor, adjust )
```

FUNCTION

This function set a value of a pixel at position cor in the image out to the value constant.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|----------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_complex | constant | Constant |
| dip_IntegerArray | cor | Pixel coordinate |
| dip_Boolean | adjust | Adjust data type of output image |

SetFloat

675

Set a pixel value

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_SetFloat ( out, constant, cor, adjust )
```

FUNCTION

This function set a value of a pixel at position cor in the image out to the value constant.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|----------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_float | constant | Constant |
| dip_IntegerArray | cor | Pixel coordinate |
| dip_Boolean | adjust | Adjust data type of output image |

SEE ALSO

SetInteger

Set a pixel value

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_SetInteger ( out, constant, cor, adjust )
```

FUNCTION

This function set a value of a pixel at position cor in the image out to the value constant.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|----------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| $\mathtt{dip}_{-}\mathtt{int}$ | constant | Constant |
| dip_IntegerArray | cor | Pixel coordinate |
| dip_Boolean | adjust | Adjust data type of output image |

Sharpen

Enhance an image

SYNOPSIS

```
#include "dip_derivatives.h"
dip_Error dip_Sharpen ( in, out, weight, bc, ps, sigmas, tc, flavour )
```

DATA TYPES

See Laplace

FUNCTION

This function enhances the high frequencies ("sharpens") of the input image in by subtracting a Laplace filtered version of in from it. The weight parameter determines by which amount the laplace information is subtracted from the original: output = input - weight * laplace(input) The sigmas are the Gaussian smoothing parameters of the Laplace operation, and determine how strongly the high-frequency noise in in is suppressed.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|-----------------|-----------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_float | weight | Laplacian weight |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_BooleanArray | process (0) | Dimensions to process |
| dip_FloatArray | sigmas | Sigma of Gaussian |
| dip_float | truncation (<0) | Truncation of Gaussian, see |
| | | GlobalGaussianTruncationGet |
| dip_DerivativeFlavour | flavour | Derivative Flavour |

Shift

an image manipulation function

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Shift ( in, out, shift, killNy )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function shifts an image in the Fourier Domain. All frequiencies larger than the Nyquist frequency are set to zero if killNy is true. It performs:

```
out = Real(InverseFourierTransform(GeneratePhase(shift) * FourierTransform( in ))
```

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------|------------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| dip_Image | out | Output image |
| dip_FloatArray | shift | Shift array |
| dip_Boolean | killNy | set frequencies > Nyquist to zero? |

SEE ALSO

Crop, Wrap, FourierTransform, Real

Sigma

Adaptive uniform smoothing filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_Sigma ( in, out, se, boundary, param, shape, sigma, outputCount
)
```

DATA TYPES

integer, float

FUNCTION

The Sigma filter is an adaptive Uniform smoothing filter. The value of the pixel underinvestigation is replaced by the average of the pixelvalues in the filter region (as specified by param, shape and se) which lie in the interval +/- 2 sigma from the value of the pixel that is filtered. If outputCount is DIP_TRUE, the output values represent the number of pixels over which the average has been calculated. When threshold is DIP_TRUE, the pixel intensities are thresholded at +/- 2 sigma, when it is set to DIP_FALSE, the intensities are weighted with the Gaussian difference with the intensity of the center pixel.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-------------|-------------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_Image | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |
| dip_float | sigma | Sigma |
| dip_Boolean | outputCount | Output the Count |

The enumerator ${\tt dip.FilterShape}$ contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

Sign

Arithmetic function

SYNOPSIS

dip_Error dip_Sign (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the sign of the input image values, and outputs a signed integer typed image. The sign of zero is defined as zero.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| dip_Image | out | Output |

SimulatedAttenuation

Simulation of the attenuation process

SYNOPSIS

#include "dip_microscopy.h"

 $dip_Error\ dip_SimulatedAttenuation$ (in, out, fAttenuation, bAttenuation, NA, refIndex, zxratio, oversample, rayStep)

DATA TYPES

binary, integer, float

FUNCTION

This function simulates an attenuation based on the model of a CSLM, using a ray tracing method.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|-----------------------------|
| dip_Image | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_float | fAttenuation | Forward attenuation factor |
| dip_float | bAttenuation | Backward attenuation factor |
| dip_float | NA | Numerical aperture |
| dip_float | refIndex | Refractive index |
| dip_float | zxratio | Z/X sampling ratio |
| dip_int | oversample | Ray casting oversampling |
| dip_float | rayStep | Ray step |

Sinc

mathematical function

SYNOPSIS

dip_Error dip_Sinc (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the sinc $(\sin(x)/x)$ of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

${\tt SingleOutputFrameWork}$

FrameWork for generation functions

SYNOPSIS

dip_Error dip_SingleOutputFrameWork (out, processBoundary, processBorder, process)

FUNCTION

This function is a frontend on the SeparableFrameWork. It provides an easier interface for filters that only need to scan an single output image. The dimension in which the image should be scanned can be specified or left to SingleOutputFrameWork by specifying the dimension with DIP_MONADIC_OPTIMAL_DIMENSION.

ARGUMENTS

| Data type | Name | Description |
|----------------------|-----------------|-----------------|
| dip_Image | out | Output |
| dip_Boundary | processBoundary | ProcessBoundary |
| dip_int | processBorder | ProcessBorder |
| dip_FrameWorkProcess | process | Process |

SEE ALSO

SeparableFrameWork, MonadicFrameWork, PixelTableFrameWork, ScanFrameWork

SingularValueDecomposition

Singular value decomposition

SYNOPSIS

dip_Error dip_SingularValueDecomposition (in, sz, u, s, v)

DATA TYPES

float

FUNCTION

Computes the SVD of the ImageArray in, such that in = u * s * transpose(v), with s being diagonal. The size of the in matrix is passed to the function via the integer array sz. If the input is of size MxN, then the outputs must be u: nxM, s: NxN, and v: NxN.

Optionally, set ${\tt u}$ and ${\tt v}$ to NULL, and let ${\tt s}$ have N elements, it will contain only the singular values.

ARGUMENTS

| Data type | Name | Description |
|---|------|----------------------|
| $\mathtt{dip}_{-}\mathtt{ImageArray}$ | in | Input |
| $\mathtt{dip}_{\scriptscriptstyle{-}}\mathtt{IntegerArray}$ | sz | Matrix size of Input |
| dip_ImageArray | u | Output |
| dip_ImageArray | s | Output |
| dip_ImageArray | v | Output |

Sinh

trigonometric function

SYNOPSIS

dip_Error dip_Sinh (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the hyperbolic sine of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------|------|-------------|
| $dip_{-}Image$ | in | Input |
| dip_Image | out | Output |

SEE ALSO

Skewing

Interpolation function

SYNOPSIS

```
#include "dip_interpolation.h"
dip_Error dip_Skewing ( in, out, shear, skew, axis, method, bgval,
periodicSkew )
```

DATA TYPES

binary, integer, float

FUNCTION

This function skews the axis axis of in over an angle angle to out using the interpolation method method. The skew is over the centre of the image. If periodicSkew is set to DIP_TRUE, the output image will be of the same size as the input image, and its pixels in the skew dimension wrapped around the image boundaries. bgval is not used in this case.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|-----------------|--------------------------------------|
| dip_Image | in | Input image |
| dip_Image | out | Output image |
| dip_float | shear (radians) | Shear angle |
| dip_int | skew | Skew dimension |
| dip_int | axis | Skew axis |
| $dipf_{-}Interpolation$ | method | Interpolation method |
| dip_BackgroundValue | bgval | Background value |
| dip_Boolean | periodicSkew | Skew using periodic image boundaries |

The dipf_Interpolation enumaration consists of the following constants:

| Name | Description |
|--------------------------------------|---------------------------------|
| DIP_INTERPOLATION_DEFAULT | Default interpolation method |
| DIP_INTERPOLATION_BSPLINE | B-Spline interpolation |
| DIP_INTERPOLATION_FOURTH_ORDER_CUBIC | Forth order cubic interpolation |
| DIP_INTERPOLATION_THIRD_ORDER_CUBIC | Third order cubic interpolation |
| DIP_INTERPOLATION_LINEAR | Linear interpolation |
| DIP_INTERPOLATION_ZERO_ORDER_HOLD | Zero order hold interpolation |

The ${\tt dip_BackgroundValue}$ enumaration consists of the following flags:

| Name | Description |
|-------------------|---------------------------------------|
| DIP_BGV_DEFAULT | Default: fill with zeros |
| DIP_BGV_ZERO | Fill with zeros |
| DIP_BGV_MAX_VALUE | Fill with maximum value for data type |
| DIP_BGV_MIN_VALUE | Fill with minimum value for data type |

SEE ALSO

Rotation, Rotation3d, Rotation3d_Axis

SmallObjectsRemove

691

Remove small objects from an image

SYNOPSIS

```
#include "dip_measurement.h"
dip_Error dip_SmallObjectsRemove ( in, out, threshold )
```

DATA TYPES

integer

FUNCTION

This function removes from the labeled image in those objects whose size (measured in the number of pixels) is smaller than threshold.

ARGUMENTS

| Data type | Name | Description |
|---|-----------|---------------------|
| ${\tt dip_Image}$ | in | Input image |
| $\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$ | out | Output image |
| $\mathtt{dip}_{-}\mathtt{int}$ | threshold | Minimum object size |

SEE ALSO

Measure, ObjectToMeasurement, Label

SobelGradient

A linear gradient filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_SobelGradient ( in, out, boundary, processDim )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

The SobelGradient filter computes a finite difference gradient $(1\ 0\ -1)/2$ in the processDim, and performs a local $(1\ 2\ 1)/4$ smoothing in the other dimensions. Note that in 2D, this differs by a multiplication factor of 1/8 to the original definition by Sobel.

ARGUMENTS

| Data type | Name | Description |
|-------------------|------------|---------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_int | processDim | ProcessDim |

SEE ALSO

FiniteDifference, Uniform, Gauss, SeparableConvolution, Convolve1d, Derivative

Sort

Sort a block of data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_Sort ( data, size, algorithm, dataType )
```

FUNCTION

Sorts a block of data (of size size and data type dataType) using the algorithm specified by algorithm.

ARGUMENTS

| Data type | Name | Description | |
|--------------|-----------|------------------------------------|--|
| void * | data | Data | |
| dip_int | size | Size | |
| dip_Sort | algorithm | Sort algorithm | |
| dip_DataType | dataType | Data type. See DIPlib's data types | |

The sortType parameter is one of:

| Name | Description |
|----------------------------|------------------------|
| DIP_SORT_DEFAULT | Default sort algorithm |
| DIP_SORT_QUICK_SORT | Quick sort |
| DIP_SORT_DISTRIBUTION_SORT | Distribution sort |
| DIP_SORT_INSERTION_SORT | Insertion sort |

SEE ALSO

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, ImageSort, SortIndices, SortIndices16, ImageSortIndices}$

SortAnything

Sort data of any type

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_SortAnything ( data, size, compareFunction, swapFunction,
tmpData, algorithm )
```

FUNCTION

Sorts a block of data (of size size) using the algorithm specified by algorithm. This routine requires the user to write two functions in order to fully implement the sorting procedure. These are SortCompareFunction and SortSwapFunction.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|-----------------|--|
| void * | data | Data |
| dip_int | size | Size |
| dip_SortCompareFunction | compareFunction | Function for comparing two data |
| | | points |
| dip_SortSwapFunction | swapFunction | Function for swapping two data points, |
| | | or copying one to the other |
| void * | tmpData | Pointer to a variable of the same type |
| | | as the data, used as temporary space |
| | | by some of the algorithms |
| dip_Sort | algorithm | Sort algorithm |

SEE ALSO

General information about sorting

 ${\tt QuickSortAnything, SortCompareFunction, SortSwapFunction}$

SortCompareFunction

Typedef for comparison function (sorting)

SYNOPSIS

```
#include "dip_sort.h"
dip_Boolean (*dip_SortCompareFunction) ( data1, index1, data2, index2 )
```

FUNCTION

A function of this type must be supplied to the sorting algorithms for data of arbitrary type. It should return DIP_TRUE if data1[index1] > data2[index2].

Example:

```
dip_Boolean MyComplexCompare( void *data1, dip_int index1, void *data2, dip_int index2 )
   dip_complex *cmplx1, *cmplx2;
   dip_float magnitude1, magnitude2;
   cmplx1 = data1;
   cmplx2 = data2;
   cmplx1 += index1;
   cmplx2 += index2;
   magnitude1 = sqrt( cmplx1->re * cmplx1->re + cmplx1->im * cmplx1->im );
   magnitude2 = sqrt( cmplx2->re * cmplx2->re + cmplx2->im * cmplx2->im );
   if ( magnitude1 > magnitude2 )
      return( DIP_TRUE );
   }
   else
      return( DIP_FALSE );
   }
}
```

ARGUMENTS

| Data type | Name | Description |
|-----------|--------|---------------------------------------|
| void * | data1 | Pointer to first data array |
| dip_int | index1 | Index to element in first data array |
| void * | data2 | Pointer to second data array |
| dip_int | index2 | Index to element in second data array |

SEE ALSO

General information about sorting

SortAnything, QuickSortAnything, SortSwapFunction

SortIndices

Sort indices to a block of data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_SortIndices ( data, indices, size, algorithm, dataType, indexType )
```

FUNCTION

Sorts a list of indices rather than the data itself using the algorithm specified by algorithm.

ARGUMENTS

| Data type | Name | Description |
|--------------|-----------|--|
| void * | data | Data |
| void * | indices | Indices |
| dip_int | size | Size |
| dip_Sort | algorithm | Sort algorithm |
| dip_DataType | dataType | Data type. See DIPlib's data types |
| dip_DataType | indexType | Data type of the index array. Must be either |
| | | DIP_DT_SINT32 or DIP_DT_SINT16. |

The sortType parameter is one of:

| Name | Description |
|----------------------------|------------------------|
| DIP_SORT_DEFAULT | Default sort algorithm |
| DIP_SORT_QUICK_SORT | Quick sort |
| DIP_SORT_DISTRIBUTION_SORT | Distribution sort |
| DIP_SORT_INSERTION_SORT | Insertion sort |

SEE ALSO

SortIndices16

Sort indices to a block of data

SYNOPSIS

```
#include "dip_sort.h"
dip_Error dip_SortIndices16 ( data, indices, size, algorithm, dataType )
```

FUNCTION

Sorts a list of (16 bit) indices rather than the data itself using the algorithm specified by algorithm.

ARGUMENTS

| Data type | Name | Description |
|--------------|-----------|------------------------------------|
| void * | data | Data |
| dip_sint16 * | indices | Indices |
| dip_int | size | Size |
| dip_Sort | algorithm | Sort algorithm |
| dip_DataType | dataType | Data type. See DIPlib's data types |

The sortType parameter is one of:

| Name | Description |
|----------------------------|------------------------|
| DIP_SORT_DEFAULT | Default sort algorithm |
| DIP_SORT_QUICK_SORT | Quick sort |
| DIP_SORT_DISTRIBUTION_SORT | Distribution sort |
| DIP_SORT_INSERTION_SORT | Insertion sort |

SEE ALSO

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, ImageSort, SortIndices, ImageSortIndices}$

SortSwapFunction

699

Typedef for swap and copy function (sorting)

SYNOPSIS

```
#include "dip_sort.h"
void (*dip_SortSwapFunction) ( data1, index1, data2, index2, copy )
```

FUNCTION

A function of this type must be supplied to the sorting algorithms for data of arbitrary type. It should swap data1[index1] and data2[index2] if copy = DIP_FALSE, and copy data1[index1] to data2[index2] if copy = DIP_TRUE.

Example:

}

}

return;

cmplx2->im = cmplx1->im; cmplx1->re = tmpValue.re; cmplx1->im = tmpValue.im;

```
void dip_MyComplexSwap( void *data1, dip_int index1, void *data2, dip_int index2, dip_Boolear
{
   dip_complex *cmplx1, *cmplx2, tmpValue;
   cmplx1 = data1;
   cmplx2 = data2;
   cmplx1 += index1;
   cmplx2 += index2;
   if ( copy == DIP_TRUE )
   {
      cmplx2->re = cmplx1->re;
      cmplx2->im = cmplx1->im;
   }
   else
   {
      tmpValue.re = cmplx2->re;
      tmpValue.im = cmplx2->im;
      cmplx2->re = cmplx1->re;
```

ARGUMENTS

| Data type | Name | Description | | |
|-------------|--------|--|--|--|
| void * | data1 | Pointer to first data array | | |
| dip_int | index1 | Index to element in first data array | | |
| void * | data2 | Pointer to second data array | | |
| dip_int | index2 | Index to element in second data array | | |
| dip_Boolean | сору | if DIP_FALSE, swap data. if DIP_TRUE copy data from data1 to | | |
| | | data2 | | |

701

Sqrt

arithmetic function

SYNOPSIS

dip_Error dip_Sqrt (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the square root of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

Exp, Exp2, Exp10, Ln, Log2, Log10

${\tt StablePixelHeapFree}$

Destroy heap structure

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapFree ( heap )
```

FUNCTION

Frees all data associated to heap and sets heap to 0.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|------|--------------------|
| dip_StablePixelHeap * | heap | The heap structure |

SEE ALSO

StablePixelHeapNew, PixelHeapNew, PixelQueueNew, StablePixelHeapPush, StablePixelHeapIop, StablePixelHeapIsEmpty

StablePixelHeapIsEmpty

Query heap

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapIsEmpty ( heap, result )
```

FUNCTION

Checks to see if there are any items on the heap. See **StablePixelHeapNew** for information on the heap data structure.

ARGUMENTS

| Data type | Name | Description |
|---------------------|--------|---|
| dip_StablePixelHeap | heap | The heap structure |
| dip_Boolean * | result | Set to true if there are no items in the heap |

SEE ALSO

StablePixelHeapNew, PixelHeapNew, PixelQueueNew, StablePixelHeapFree, StablePixelHeapPush, StablePixelHeapPop

StablePixelHeapNew

Create a new heap structure

SYNOPSIS

#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapNew (heap, ndims, blocksize, order, resources)

FUNCTION

This function allocates space for a new dip_StablePixelHeap structure. Memory allocated is tracked in resources. The heap is dimensioned to hold pixels from an ndims-dimensional image, and initially enough space is allocated for blocksize elements. The heap will be expanded as necessary when used.

The heap stores the coordinates, the value and the pointer to a pixel in an image. Note that the value does not need to equal the data pointed to by the pointer. ndims can be set to zero, in which case no coordinates are stored; this does not affect the function of the value and the pointer.

A heap is a priority queue data structure. Just like a queue, items can be added (pushed) and subtracted (popped). However, in the priority queue the item popped is always the higherst priority one: either the one with the highest-valued item (order is DIP_GVSO_HIGH_FIRST) or lowest-valued item (order is DIP_GVSO_LOW_FIRST). When various identically-valued items are stored on the heap, they will be extracted in the same order as they were insterted (FIFO - first in, first out). If this order is unimportant (such as for the GrowRegionsWeighted algorithm, use the more efficient dip_PixelHeap instead. See PixelHeapNew for information on the unstable heap structure.

ARGUMENTS

| Data type | Name | Description |
|-------------------------|-----------|------------------------------------|
| dip_StablePixelHeap * | heap | The newly allocated heap structure |
| dip_int | ndims | Image dimensionality |
| dip_int | blocksize | Size of each allocation block |
| dipf_GreyValueSortOrder | order | Determines the heap's sort order |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

The dipf_GreyValueSortOrder enumeration consists of the following values:

| Name | Description |
|---------------------|--|
| DIP_GVSO_HIGH_FIRST | Process the pixels from high grey-value to low grey-value. |
| DIP_GVSO_LOW_FIRST | Process the pixels from low grey-value to high grey-value. |

IMPLEMENTATION

This data structure is implemented identically to PixelHeapNew (see that function's description for details), but an insertion order value is attached to each pixel pushed onto the heap. This is used to maintain stability.

SEE ALSO

PixelHeapNew, PixelQueueNew, StablePixelHeapFree, StablePixelHeapPush, StablePixelHeapPop, StablePixelHeapIsEmpty

StablePixelHeapPop

Pop item onto heap

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapPop ( heap, coords, pointer, value )
```

FUNCTION

Pops the next pixel from the heap. See StablePixelHeapNew for information on the heap data structure. coords is a pointer to an array of dip_ints, such as that obtained with dip_IntegerArray->array. It should have as many elements as the image dimensionality. If the stack was created with ndims set to 0, the coords pointer is ignored. coords, pointer and value can be NULL if you are not interested in either those values.

ARGUMENTS

| Data type | Name | Description |
|---------------------|---------|---|
| dip_StablePixelHeap | heap | The heap structure |
| dip_int * | coords | Receives the coordinates of the popped item |
| void ** | pointer | Receives the pointer of the popped item |
| dip_sfloat * | value | Receives the value of the popped item |

SEE ALSO

StablePixelHeapNew, PixelHeapNew, PixelQueueNew, StablePixelHeapFree, StablePixelHeapPush, StablePixelHeapIsEmpty

StablePixelHeapPush

Push item onto heap

SYNOPSIS

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapPush ( heap, coords, pointer, value )
```

FUNCTION

Pushes a pixel onto the heap. See StablePixelHeapNew for information on the heap data structure. All 3 values coords, pointer and value are stored, except if the heap was created with ndims set to 0, in which case the coords pointer is ignored.

coords is a pointer to an array of dip_ints, such as that obtained with dip_IntegerArray->array. It should have as many elements as the image dimensionality. pointer is a pointer to any memory location, and value is the value to be used when sorting.

ARGUMENTS

| Data type | Name | Description |
|---------------------|---------|--------------------------|
| dip_StablePixelHeap | heap | The heap structure |
| dip_int * | coords | Coordinates to be pushed |
| void * | pointer | Pointer to be pushed |
| dip_sfloat | value | Value to be pushed |

StandardDeviation

statistics function

SYNOPSIS

dip_Error dip_StandardDeviation (in, mask, out, ps)

DATA TYPES

binary, integer, float

FUNCTION

Calculates the standard deviation of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask |
| dip_Image | out | Output |
| dip_BooleanArray | ps (0) | Dimensions to project |

SEE ALSO

StringAppend

709

Append a string to another

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringAppend ( str1, str2, cstr )
```

FUNCTION

Concatenates str1 and str2 and puts the result in str1, which is increased in size if necessary. If str2 is 0, cstr is used instead.

ARGUMENTS

| Data type | Name | Description |
|---|------|---------------|
| $\mathtt{dip}_{\mathtt{S}}\mathtt{tring}$ | str1 | First string |
| dip_String | str2 | Second string |
| char * | cstr | Second string |

SEE ALSO

StringArrayCopy

Copy a string array

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringArrayCopy ( new, src, resources )
```

FUNCTION

This function copies the complete src string array to new.

ARGUMENTS

| Data type | Name | Description |
|-------------------|-----------|--|
| dip_StringArray * | new | Pointer to the destination dip_StringArray structure |
| dip_StringArray | src | Source string array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

StringArrayFree

Array free function

SYNOPSIS

dip_Error dip_StringArrayFree (array)

FUNCTION

This function frees *array, and sets array to zero.

ARGUMENTS

| Data type | Name | Description |
|------------------|-------|--------------|
| dip_ImageArray * | array | string array |

SEE ALSO

StringArrayNew, StringArrayCopy

ArrayFree, IntegerArrayFree, FloatArrayFree, ComplexArrayFree,
BoundaryArrayFree, FrameWorkProcessArrayFree, DataTypeArrayFree, ImageArrayFree,
BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

StringArrayNew

Allocate an array of strings

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringArrayNew ( array, size, stringSize, init, resources )
```

FUNCTION

This function allocates an array of strings. size specifies the size of the array, stringSize the size of the individual strings, which are allocated too. If StringSize is zero, and init is not, the strings in the array are initialised with init (in size and content). If both stringSize and init are zero, strings of zero length are created. (see StringNew).

ARGUMENTS

| Data type | Name | Description |
|-------------------|------------|--|
| dip_StringArray * | array | Pointer to the array |
| dip_int | size | Size of the array |
| dip_int | stringSize | Size of the strings |
| char * | init | Initialisation string |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

StringCat

Concatenate two strings

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringCat ( newStr, str1, str2, cstr, resources )
```

FUNCTION

Concatenates str1 and str2 and puts the result in newStr, which is allocated. If str2 is 0, cstr is used instead.

ARGUMENTS

| Data type | Name | Description |
|---------------------|-----------|--|
| dip_String * | newStr | Destination |
| dip_String | str1 | First string |
| $	ext{dip_String}$ | str2 | Second string |
| char * | cstr | Second string |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

 ${\tt StringAppend, StringCompare, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, StringReplace, UnderscoreSpaces}$

StringCompare

Compare two strings

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringCompare ( orig, copy, verdict )
```

FUNCTION

This function uses the strcmp function to compare orig and copy. If the strings are different, an error is generated, or verdict obtains the value DIP_FALSE, if it is not zero.

ARGUMENTS

| Data type | Name | Description |
|---------------|---------|---------------------------|
| dip_String | orig | The original string |
| dip_String | сору | The fake (or not) string |
| dip_Boolean * | verdict | Verdict of the comparison |

SEE ALSO

 ${\tt StringAppend, StringCat, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, StringReplace, UnderscoreSpaces}$

${\tt StringCompareCaseInsensitive}$

Compare two strings without minding case

715

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringCompareCaseInsensitive ( orig, copy, verdict )
```

FUNCTION

This function uses the strcasecmp (or stricmp) function to compare orig and copy. If the strings are different, an error is generated, or verdict obtains the value DIP_FALSE, if it is not zero.

ARGUMENTS

| Data type | Name | Description |
|---------------|---------|---------------------------|
| dip_String | orig | The original string |
| dip_String | сору | The fake (or not) string |
| dip_Boolean * | verdict | Verdict of the comparison |

SEE ALSO

StringAppend, StringCat, StringCompare, StringCopy, StringCrop, StringNew, StringReplace, UnderscoreSpaces

StringCopy

Copy a String

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringCopy ( new, src, resources )
```

FUNCTION

Thsi function copies string src to new.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--|
| dip_String * | new | Pointer to a destination dip_String strcture |
| dip_String | src | Source string |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCrop, StringNew, StringReplace, UnderscoreSpaces

StringCrop

Crop a string

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringCrop ( str, length )
```

FUNCTION

Crops str to length characters.

ARGUMENTS

| Data type | Name | Description |
|---|--------|----------------------|
| dip_String | str | String to be cropped |
| $\mathtt{dip}_{\mathtt{-}}\mathtt{int}$ | length | New string length |

SEE ALSO

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCopy, StringNew, StringReplace, UnderscoreSpaces

StringFree

Free a string

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringFree ( void )
```

FUNCTION

This function frees a string data structure that has been allocated using StringNew.

ARGUMENTS

| Data type | Name | Description |
|--------------|--------|-----------------------------------|
| dip_String * | string | Pointer to the string to be freed |

SEE ALSO

StringNew

StringNew

Allocate a string

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringNew ( string, size, init, resources )
```

FUNCTION

This function allocates a string of size size. If init is not zero, its contents is copied into the new string. If size is zero, and init is not, the size of string is made equal to init plus one.

ARGUMENTS

| Data type | Name | Description |
|---------------|-----------|--|
| dip_String * | string | Pointer to the new string |
| dip_int | size | Size of the string |
| char * | init | Initialisation string |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

SEE ALSO

 ${\tt StringArrayNew}, {\tt StringAppend}, {\tt StringCat}, {\tt StringCompare}, \\ {\tt StringCompareCaseInsensitive}, {\tt StringCopy}, {\tt StringCrop}, {\tt StringReplace}, \\ {\tt UnderscoreSpaces}$

StringReplace

Replace the contents of one string with that of another

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_StringReplace ( str1, str2, cstr )
```

FUNCTION

Replaces the content of str1 with str2. str1 is increased in size if necessary. If str2 is 0, cstr is used instead.

ARGUMENTS

| Data type | Name | Description |
|---|------|--------------------|
| $\mathtt{dip}_{\mathtt{S}}\mathtt{tring}$ | str1 | Destination string |
| dip_String | str2 | Source string |
| char * | cstr | Source string |

SEE ALSO

StructureTensor2D

Two dimensional Structure Tensor

SYNOPSIS

```
#include "dip_structure.h"
dip_Error dip_StructureTensor2D( in, mask, orientation, energy, 11, 12,
anisotropy1, anisotropy2, boundary, gradSpec, gradSigmas, tensorSpec,
tensorSigmas )
```

DATA TYPES

integer, float

FUNCTION

This function computes the Structure Tensor (ST) at each point in the image. For a description of this technique see the references. There are two stages in the computation. The first stage computes the gradient vector at each point, using Derivative with parameters gradSpec and gradSigmas. The second stage, the tensor smoothing, is also performed using Derivative (with order = 0). The parameters used are tensorSpec and tensorSigmas.

If a mask image is given, a technique called normalised convolution (see references) is used to "fill in" the missing data.

The routine has a number of output images. Each of these can be set to zero. If set to zero, the corresponding result will not be computed. The following quantities are computed by this routine:

| orientation | Orientation. Lies in the interval |
|-------------|---|
| | (-pi/2,pi/2). |
| energy | Sum of the two eigenvalues 11 and 12. |
| 11 | The largest eigenvalue. |
| 12 | The smallest eigenvalue. |
| anisotropy1 | Measure for local anisotropy: (11 - 12) |
| | / (11 + 12). |
| anisotropy2 | Measure for local anisotropy: 1 - 12 / |
| | 11. |

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|---|
| dip_Image | in | Input |
| dip_Image | mask | Mask image (0=missing data) |
| $\mathtt{dip}_{-}\mathtt{Image}$ | orientation | Orientation |
| dip_Image | energy | Energy (11+12) |
| dip_Image | 11 | Largest eigenvalue |
| dip_Image | 12 | Smallest eigenvalue |
| dip_Image | anisotropy1 | Local anisotropy: (11-12)/(11+12) |
| dip_Image | anisotropy2 | Local anisotropy: 1-12/11 |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_DerivativeSpec | gradSpec | Parameters for derivative to compute gradient |
| | | (see DerivativeSpec data structure) |
| dip_FloatArray | gradSigmas | Sigmas of derivative to compute gradient |
| | | Sigma of derivative to compute gradient |
| dip_DerivativeSpec | tensorSpec | Parameters for Gaussian for tensor smoothing |
| | | (see DerivativeSpec data structure) |
| dip_FloatArray | tensorSigmas | Sigmas of Gaussian for tensor smoothing |
| | | Sigma of Gaussian for tensor smoothing |

SubpixelLocation

Gets coordinates of an extremum with sub-pixel precision

SYNOPSIS

```
#include "dip_analysis.h"
dip_Error dip_SubpixelLocation ( in, pos, coords, val, method, polarity )
```

DATA TYPES

integer, float

FUNCTION

Determines the sub-pixel location of a local maximum or minimum close to pos. pos should point to a pixel that is larger than its direct neighbours (if polarity is DIP_SEP_MAXIMUM) or smaller than its direct neighbours (polarity is DIP_SEP_MINIMUM). coords will contain the the sub-pixel location of this local extremum. val will contain the interpolated grey value at the location of the extremum. method determines which method is used.

ARGUMENTS

| Data type | Name | Description |
|-------------------------------|--------|----------------------------|
| dip_Image | in | Input grayscale image |
| dip_IntegerArray | pos | Input coordinates |
| dip_FloatArray | coords | Output coordinates |
| dip_float* | val | Output grey value |
| dipf_SubpixelExtremumMethod | method | Sub-pixel detection method |
| dipf_SubpixelExtremumPolarity | pol | Maximum or minimum? |

The dipf_SubpixelExtremumMethod flag can be any of these values:

| Name | Description |
|-----------------------------|--|
| DIP_SEM_DEFAULT | Same as DIP_SEM_PARABOLIC_SEPARABLE. |
| DIP_SEM_LINEAR | Computes the center of gravity of 3 pixels around the |
| | extremum, in each dimension independently. The val |
| | returned is that of the pixel at pos. |
| DIP_SEM_PARABOLIC_SEPARABLE | Fits a parabola to 3 pixels around the extremum, for |
| | each dimension independently. The val returned is the |
| | maximum (minimum) value of these 1D extrema, and |
| | thus not equivalent to the grey value obtained by true |
| | interpolation. |
| DIP_SEM_PARABOLIC | Fits a parabolic patch to a region 3x3 or 3x3x3 pixels |
| | around the extremum (only for 2D or 3D images). |
| DIP_SEM_GAUSSIAN_SEPARABLE | Same as DIP_SEM_PARABOLIC_SEPARABLE, but using the |
| | log of the pixel values, very accurate if peak is a |
| | Gaussian. |
| DIP_SEM_GAUSSIAN | Same as DIP_SEM_PARABOLIC, but using the log of the |
| | pixel values (only for 2D or 3D images). |
| DIP_SEM_BSPLINE | Fits a B-spline to 11 pixels around the extremum, in |
| | each dimension independently. The val returned is the |
| | maximum (minimum) value of these 1D extrema, and |
| | thus not equivalent to the grey value obtained by true |
| | interpolation |

SEE ALSO

SubpixelMaxima, SubpixelMinima

SubpixelMaxima

Gets coordinates of local maxima with sub-pixel precision

SYNOPSIS

```
#include "dip_analysis.h"
dip_Error dip_SubpixelMaxima ( in, mask, out_coord, out_val, method )
```

DATA TYPES

integer, float

FUNCTION

Detects local maxima in the image, and returns their coordinates, with sub-pixel precision, in the output image out_coord. Only pixels where mask is on will be examined. Local maxima are detected using Maxima, then their position is determined accurately using SubpixelLocation. out_coord will have ndims pixels along the first dimension (ndims being the number of dimensions in in), and as many pixels along the second dimension as there are local maxima in in. Thus, each row of the image out_coord contains the coordinates of one local maximum. out_coord is always dip_float. out_val, when not 0, will contain the interpolated values of the image at the local maxima. out_val will have the same size and type as out_coord, except only one pixel along the first dimension.

A local maximum can not touch the edge of the image. That is, its integer location must be one pixel away from the edge.

See SubpixelLocation for the definition of the method parameter.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-----------|--|
| dip_Image | in | Input grayscale image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask | Binary mask for ROI processing |
| dip_Image | out_coord | Output coordinates, image will be N_dims |
| | | x N_maxima |
| dip_Image | out_val | Output values, image will be 1 x |
| | | N_maxima |
| dipf_SubpixelExtremumMethod | method | Sub-pixel detection method |

SubpixelMinima

Gets coordinates of local minima with sub-pixel precision

SYNOPSIS

```
#include "dip_analysis.h"
dip_Error dip_SubpixelMinima ( in, mask, out_coord, out_val, method )
```

DATA TYPES

integer, float

FUNCTION

Detects local minima in the image, and returns their coordinates, with sub-pixel precision, in the output image out_coord. Only pixels where mask is on will be examined. Local minima are detected using Minima, then their position is determined accurately using SubpixelLocation. out_coord will have ndims pixels along the first dimension (ndims being the number of dimensions in in), and as many pixels along the second dimension as there are local minima in in. Thus, each row of the image out_coord contains the coordinates of one local minimum. out_coord is always dip_float. out_val, when not 0, will contain the interpolated values of the image at the local minima. out_val will have the same size and type as out_coord, except only one pixel along the first dimension.

A local minimum can not touch the edge of the image. That is, its integer location must be one pixel away from the edge.

See SubpixelLocation for the definition of the method parameter.

ARGUMENTS

| Data type | Name | Description |
|-----------------------------|-----------|--|
| dip_Image | in | Input grayscale image |
| dip_Image | mask | Binary mask for ROI processing |
| dip_Image | out_coord | Output coordinates, image will be N_dims |
| | | x N_minima |
| dip_Image | out_val | Output values, image will be 1 x |
| | | N_minima |
| dipf_SubpixelExtremumMethod | method | Sub-pixel detection method |

Subsampling

Interpolation function

SYNOPSIS

```
#include "dip_interpolation.h"
dip_Error dip_Subsampling ( in, out, sample )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function subsamples in by copying each sampleth pixel to out.

ARGUMENTS

| Data type | Name | Description |
|---|--------|----------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | in | Input image |
| dip_Image | out | Output image |
| dip_IntegerArray | sample | Sample spacing |

SEE ALSO

Sum

statistics function

SYNOPSIS

dip_Error dip_Sum (in, mask, out, ps)

DATA TYPES

binary, integer, float, complex

FUNCTION

Calculates the sum of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| dip_Image | in | Input |
| dip_Image | mask (0) | Mask |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |
| dip_BooleanArray | ps (0) | Dimensions to project |

SEE ALSO

Tan

trigonometric function

SYNOPSIS

dip_Error dip_Tan (in, out)

DATA TYPES

binary, integer, **float**, **complex**

FUNCTION

Computes the tangent of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| dip_Image | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

Sin, Cos, Tan, Asin, Acos, Atan, Atan2, Sinh, Cosh, Tanh

Tanh

trigonometric function

SYNOPSIS

dip_Error dip_Tanh (in, out)

DATA TYPES

binary, integer, float

FUNCTION

Computes the hyperbolic tangent of the input image values.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|-------------|
| ${\tt dip_Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output |

SEE ALSO

TensorImageInverse

Invert tensor image

SYNOPSIS

 $\mbox{dip_Error dip_TensorImageInverse}$ (in, out)

DATA TYPES

float

FUNCTION

Inverts the NxN tensor image in (stored as an array with N*N elements) using LU decomposition.

ARGUMENTS

| Data type | Name | Description |
|----------------------------|------|-------------|
| dip_ImageArray | in | Input |
| $\mathtt{dip_ImageArray}$ | out | Output |

TestObjectAddNoise

TestObject generation function

SYNOPSIS

#include "dip_generation.h"

dip_Error dip_TestObjectAddNoise (object, noisy, background, backvalue, gaussianNoise, poissonNoise, snr, conversion, variance, random)

DATA TYPES

binary, integer, float

FUNCTION

This function adds a mixture of Gaussian and Poisson noise to a testobject at a specified signal-to-noise ratio. The SNR is defined as the average object energy divided by the average noise power.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------------|--|
| dip_Image | object | Input Object Image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | noisy | Output Image |
| dip_Image | background | Background Image |
| dip_float | backvalue | Constant Background Value |
| dip_float | gaussianNoise | Relative Amount of Gaussian Noise |
| dip_float | poissonNoise | Relative Amount of Poisson Noise |
| dip_float | snr | Signal to Noise Ratio |
| dip_float * | conversion (0) | Pointer to the Poisson Conversion Factor |
| dip_float * | variance (0) | Pointer to the Gaussian Variance |
| dip_Random * | random | Pointer to a random value structure |

SEE ALSO

TestObjectCreate, TestObjectModulate, TestObjectBlur

TestObjectBlur

TestObject generation function

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_TestObjectBlur ( object, psf, convolved, xNyquist, testPSF )
```

DATA TYPES

binary, integer, float

FUNCTION

This function blurs a testobject with a Gaussian psf, with a two dimensional in focus diffraction limited incoherent PSF or with an user-supplied PSF. The xNyquist parameter specifies the oversampling factor of the incoherent PSF and Gaussian PSF. The sigma of the Gaussian PSF is equal to 0.9 * xNyquist.

ARGUMENTS

| Data type | Name | Description |
|--------------|-----------|---------------------|
| dip_Image | object | Input Object Image |
| dip_Image | psf | User supplied PSF |
| dip_Image | convolved | Output Image |
| dip_float | xNyquist | Oversampling Factor |
| dipf_TestPSF | testPSF | TestPSF |

The dipf_TestPSF enumaration consists of the following flags:

| Name | Description |
|-----------------------------|---|
| DIP_TEST_PSF_GAUSSIAN | Gaussian PSF |
| DIP_TEST_PSF_INCOHERENT_OTF | in-focus, diffraction limited, incoherent PSF |
| DIP_TEST_PSF_USER_SUPPLIED | User supplied PSF with the psf image |
| DIP_TEST_PSF_NONE | no blurring |

SEE ALSO

TestObjectCreate, TestObjectModulate, TestObjectAddNoise

TestObjectCreate

TestObject generation function

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_TestObjectCreate ( object, testObject, objectHeight,
objectRadius, scale, scaleRadius, scaleAmplitude, objSigma, position, random)
```

DATA TYPES

Output: sfloat

FUNCTION

This function can generate an aliasing free object (ellips, box, ellipsoid shell, box shell) or uses an user-supplied object. The generated objects have their origin at the center in the image, but can be generated with a sub-pixel random shift around the center, to average out dicretization effects over several instances of the same generated object. Optinally the generated object can be convolved with an isotropic Gaussian with a width specified by objSigma. Elliptical objects are only supported for images with a dimsnionality equal or less than three. The position boolean variable specifies whether a subpixel random shift should be applied to the object. This can be used to average out digitisation error over a repetition of the generation of the same object.

ARGUMENTS

| Data type | Name | Description |
|-----------------|----------------|-------------------------------------|
| dip_Image | object | Output Object Image |
| dipf_TestObject | testObject | Type of Test Object |
| dip_float | objectHeight | Object Height |
| dip_float | objectRadius | Object Radius |
| dip_FloatArray | scale | Relative Radii for each dimension |
| dip_float | scaleRadius | ScaleRadius |
| dip_float | scaleAmplitude | ScaleAmplitude |
| dip_float | objSigma | Sigma of Gaussian Object Blur |
| dip_Boolean | position | Random Subpixel Position Shift |
| dip_Random * | random | Pointer to a random value structure |

SEE ALSO

TestObjectModulate

TestObject generation function

SYNOPSIS

```
#include "dip_generation.h"
dip_Error dip_TestObjectModulate ( in, out, modulation, modulationDepth )
```

DATA TYPES

Output: sfloat

FUNCTION

This function adds a sine modulation to a test object, with modulation the modulation frequency and modulationDepth the modulation depth.

ARGUMENTS

| Data type | Name | Description |
|---|-----------------|----------------------|
| $\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$ | in | Input |
| dip_Image | out | Output |
| dip_FloatArray | modulation | Modulation Frequency |

Threshold

Point Operation

SYNOPSIS

```
#include "dip_point.h"
dip_Error dip_Threshold ( in, out, threshold, foreground, background, binaryOutput )
```

DATA TYPES

integer, float

FUNCTION

This function thresholds an image at the threshold value. If the boolean binaryOutput is true, Threshold will produce a binary image. Otherwise an image of the same type as the input image is produced, with the pixels set to either foreground or background. In other words: out = (in >= threshold ? foreground: background)

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|--------------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | out | Output image |
| dip_float | threshold | Threshold value |
| dip_float | foreground | Foreground value |
| dip_float | background | Background value |
| dip_Boolean | binaryOutput | Convert output image to binary |

TikhonovMiller

Image restoration filter

SYNOPSIS

```
#include "dip_restoration.h" #include "dip_transform.h"
dip_Error dip_TikhonovMiller ( in, psf, out, reg, background, method, var, lambda, flags )
```

FUNCTION

The TikhonovMiller restoration filter is a linear least squares restoration algorithm.

ARGUMENTS

| Data type | Name | Description |
|--|----------------|------------------------------|
| dip_Image | in | Input image |
| dip_Image | psf | Point spread function image |
| dip_Image | out | Output image |
| dip_Image | reg | Regularisation filter image |
| dip_Image | background (0) | Background image |
| dipf_RegularizationParameter | method | Method used to determine the |
| | | regularisation parameter |
| dip_float | var | Noise variance |
| dip_float * | lambda | Regularisation parameter |
| $	ext{dipf}_{-}	ext{ImageRestoration}$ | flags | Restoration flags |

Determine the value of the regularisation parameter

SYNOPSIS

```
#include "dip_restoration.h"
dip_Error dip_TikhonovRegularizationParameter ( in, psf, reg, background,
max, min, lambda, method, var, flags )
```

FUNCTION

This function implements different methods to estimate the value of the regularistion parameter lambda of the TikhonovMiller restoration filter.

ARGUMENTS

| Data type | Name | Description |
|-------------------------------|----------------|---------------------------------|
| dip_Image | in | Input image |
| dip_Image | psf | Point spread function image |
| dip_Image | reg | Regularisation filter rimage |
| $\mathtt{dip}_{-}Image$ | background (0) | Background image |
| dip_float | max | Maximum value of lambda |
| dip_float | min | Minimum value of lambda |

TimerGet

Timing functions

SYNOPSIS

```
#include "dip_timer.h"
dip_Error dip_TimerGet ( timer )
```

FUNCTION

This function gets three timer values elapsed since the last call to TimerSet.

The dip_Timer struct contains the following values:

| Data type | Name | Description |
|----------------------------------|---------------|--|
| dip_int | setTime | Time stamp when TimerSet was called. |
| dip_int | getTime | Time stamp when TimerGet was called. |
| dip_float | getClockTime | Amount of CPU time (in seconds) between TimerSet |
| | | and TimerGet. |
| dip_float | getSystemTime | Amount of CPU time (in seconds) executing system calls |
| | | in the process. |
| dip_float | getUserTime | Amount of CPU time (in seconds) executing instructions |
| | | in the process. |
| dip_float | setClockTime | Set by TimerSet, just ignore! |
| dip_float | setSystemTime | Set by TimerSet, just ignore! |
| $\mathtt{dip}_{-}\mathtt{float}$ | setUserTime | Set by TimerSet, just ignore! |

setTime and getTime give the time, in seconds, elapsed since the Epoch (00:00:00 UTC, January 1, 1970). The C function ctime can convert this value into a date string.

getClockTime gives the CPU time, in seconds, between the call to TimerSet and TimerGet. The number of significant digits depends on your system. getUserTime contains the portion of this time that was used by the CPU to process instructions for the current process. getSystemTime contains the portion of time spent in the system while executing tasks on behalf of the current process (e.g. doing file I/O). getUserTime and getSystemTime do not necessarily add up to getClockTime if there are other processes running on the same processor.

ARGUMENTS

| Data type | Name | Description |
|-------------|-------|-------------------------------|
| dip_Timer * | timer | Pointer to a dip_Timer struct |

NOTES

Note that getClockTime, getUserTime and getSystemTime can wrap around. The system returns these values as a clock_t value. If this is a 32-bit integer, these timers wrap around after only 72 minutes.

747

getUserTime and getSystemTime are not supported on some systems, it is possible that these values are always 0.

SEE ALSO

TimerSet

TimerSet

Timing functions

SYNOPSIS

```
#include "dip_timer.h"
dip_Error dip_TimerSet ( timer )
```

FUNCTION

This function resets three timers that can be obtained by TimerGet.

ARGUMENTS

TimerGet

DIPlib function reference

Tophat

Morphological high-pass filter

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Tophat ( in, out, se, boundary, param, shape, edgeType,
polarity )
```

DATA TYPES

integer, float

FUNCTION

The top-hat is the difference between a morphological operation and the original image, comparable to a high-pass filter. Which operation is used can be chosen through the dip_MphEdgeType and dip_MphTophatPolarity parameters.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, param determines the sizes of the structuring elements.

When shape is DIP_FLT_SHAPE_DISCRETE_LINE or DIP_FLT_SHAPE_INTERPOLATED_LINE, the structuring element is a line. param->array[0] determines the length, param->array[1] the angle. This is currently only supported for 2D images. Interpolated lines use interpolation to obtain a more accurate result, but loose the strict increasingness and extensivity (these properties are satisfied only by approximation).

When shape is set to DIP_FLT_SHAPE_PARABOLIC, params specifies the curvature of the parabola.

When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, so is used as structuring element. It can be either a binary or a grey-value image. Its origin is the center, or one pixel to the left of the center if the size is even.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-----------------------|----------|----------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom structuring element |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Structuring element |
| dip_MphEdgeType | edgeType | edgeType |
| dip_MphTophatPolarity | polarity | polarity |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

The enumerator ${\tt dip_MphEdgeType}$ contains the following constants:

| Name | Description |
|-----------------|---|
| DIP_MPH_TEXTURE | Response is limited to edges in texture |
| DIP_MPH_OBJECT | Response is limited to object edges |
| DIP_MPH_BOTH | All edges produce equal response |

The enumerator dip_MphTophatPolarity contains the following constants:

| Name | Description |
|-----------------|---|
| DIP_MPH_TEXTURE | Response is limited to edges in texture |
| DIP_MPH_OBJECT | Response is limited to object edges |
| DIP_MPH_BOTH | All edges produce equal response |

SEE ALSO

Lee, MorphologicalGradientMagnitude, MorphologicalRange, MultiScaleMorphologicalGradient, MorphologicalSmoothing, MorphologicalThreshold

tpi.h

Type iterator

SYNOPSIS

#include "dip_tpi.h"

FUNCTION

Type iterator. For each data type specified by the define DIP_TPI_ALLOW, dip_tpi.h will include the file specified by the define DIP_TPI_FILE. If DIP_TPI_ALLOW is not defined the file will be included for all data types. DIP_TPI_TYPES must be defined as a logical OR of identifier flags and identifier group flags, as given in DIPlib's data types and the table below. During each "iteration" the main symbols defined by dip_tpi.h are DIP_TPI, DIP_TPI_DATA_TYPE, DIP_TPI_IDENTIFIER and DIP_TPI_EXTENSION. The following table shows how these are defined for each data type:

| DIP_TPI | DIP_TPI_DATA_TYPE | | DIP_TPI_EXTENSION |
|--------------|-------------------|--------------------|-------------------|
| | | DIP_TPI_IDENTIFIER | |
| dip_bin8 | DIP_DT_BIN8 | DIP_DTID_BIN8 | _b8 |
| dip_bin16 | DIP_DT_BIN16 | DIP_DTID_BIN16 | _b16 |
| dip_bin32 | DIP_DT_BIN32 | DIP_DTID_BIN32 | _b32 |
| dip_uint8 | DIP_DT_UINT8 | DIP_DTID_UINT8 | _u8 |
| dip_uint16 | DIP_DT_UINT16 | DIP_DTID_UINT16 | _u16 |
| dip_uint32 | DIP_DT_UINT32 | DIP_DTID_UINT32 | _u32 |
| dip_sint8 | DIP_DT_SINT8 | DIP_DTID_SINT8 | _s8 |
| dip_sint16 | DIP_DT_SINT16 | DIP_DTID_SINT16 | _s16 |
| dip_sint32 | DIP_DT_SINT32 | DIP_DTID_SINT32 | _s32 |
| dip_sfloat | DIP_DT_SFLOAT | DIP_DTID_SFLOAT | _sfl |
| dip_dfloat | DIP_DT_DFLOAT | DIP_DTID_DFLOAT | _dfl |
| dip_scomplex | DIP_DT_SCOMPLEX | DIP_DTID_SCOMPLEX | _SCX |
| dip_dcomplex | DIP_DT_DCOMPLEX | DIP_DTID_DCOMPLEX | _dcx |

Using this include file it is possible to compile source code for different data types. We recommend that instead of splitting your code into two files, one for generic code and one for type specific code, that you use dip_tpi.h to let the source file include itself. This also prevents dependency problems with makefiles. A source file that includes itself through dip_tpi.h should have the following format:

```
contents of example.c:
#ifndef DIP_TPI
```

#include "diplib.h"

```
#define DIP_TPI_FILE "example.c"
#include "dip_tpi.h"

/* This is where the generic code should be */
#else

/* This is where the type specific code should be */
#endif
```

In addition to the main defines as described above, there are a number of macro's that are defined by dip_tpi.h:

| DIP_TPI_FUNC (function name) | attaches the current type suffix to the |
|-----------------------------------|--|
| | function name. |
| DIP_TPI_DEFINE (function name) | equivalent to: dip_Error DIP_TPI_FUNC(|
| | function name) useful for function |
| | definitions. |
| DIP_TPI_DECLARE (function name) | equivalent to: dip_Error DIP_TPI_FUNC(|
| | function name) useful for function |
| | declarations. Don't forget the trailing ";". |
| DIP_TPI_NAME (function name) | attaches the current type suffix to the |
| | function name and puts double quotes |
| | around the result, thus creating a string. |

There are also a couple of defines that are only available for some of the data types:

| When DIP_TPI is | |
|-----------------|---|
| dip_sfloat | DIP_TPI_CAST_R2C is defined as |
| | dip_scomplex |
| dip_dfloat | DIP_TPI_CAST_R2C is defined as |
| | dip_dcomplex |
| dip_scomplex | DIP_TPI_CAST_C2R is defined as dip_sfloat |
| dip_dcomplex | DIP_TPI_CAST_C2R is defined as dip_dfloat |

Other type iterators may be created by making a copy of the dip_tpi.h file and replacing DIP_TPI throughout the file by a different name for the new type iterator.

ARGUMENTS

| Name | Description | |
|---------------|---|--|
| DIP_TPI_ALLOW | logical OR of data type identifier and identifier group flags to indicate | |
| | for which data types the file should be included | |
| DIP_TPI_FILE | Name of the file to be included by dip_tpi.h | |

SEE ALSO

DIPlib's data types

UnderscoreSpaces

755

Replace spaces with underscores

SYNOPSIS

```
#include "dip_string.h"
dip_Error dip_UnderscoreSpaces ( string )
```

FUNCTION

This function replaces spaces in string with underscores. This function works in-place.

ARGUMENTS

| Data type | Name | Description |
|---------------|--------|-----------------------|
| dip_String | string | String to be examined |

SEE ALSO

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, StringReplace

Uniform

Uniform filter

SYNOPSIS

```
#include "dip_linear.h"
dip_Error dip_Uniform ( in, out, se, boundary, param, shape )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This functions implements an uniform convolution filter with support for various filter shapes.

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|------------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom filter shape (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter parameters |
| dip_FilterShape | shape | Filter shape |

The enumerator dip_FilterShape contains the following constants:

DIP*lib* function reference 757

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

UniformNoise

Generate an image disturbed by uniform noise

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_UniformNoise ( in, out, lowerBound, upperBound, random )
```

DATA TYPES

integer, float

FUNCTION

Generate an image disturbed by additive uniform noise. See UniformRandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description |
|--------------|------------|--|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_float | lowerBound | Lower bound of the uniform distribution the noise is |
| | | drawn from |
| dip_float | upperBound | Upper bound of the uniform distribution the noise is |
| | | drawn from |
| dip_Random * | random | Pointer to a random value structure |

EXAMPLE

Get a image with additive uniform noise as follows:

```
dip_Image in, out;
dip_float lower, upper;
dip_Random random;

lower = 1.0;
upper = 10.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_UniformNoise( in, out, lower, upper, &random ));
```

SEE ALSO

 $\label{thm:comparison} Uniform Random Variable, Random Seed, Random Seed Vector, \\ Gaussian Noise, Poisson Noise, Binary Noise$

UniformRandomVariable

Uniform random variable generator

SYNOPSIS

```
#include "dip_noise.h"
dip_Error dip_UniformRandomVariable ( random, lowerBound, upperBound, output)
```

FUNCTION

Generate an uniform distributed random variable. See RandomVariable for more information on the random number generator.

ARGUMENTS

| Data type | Name | Description | |
|--------------|------------|---|--|
| dip_Random * | random | Pointer to a random value structure | |
| dip_float | lowerBound | Lower bound of the uniform distribution the variable is | |
| | | drawn from | |
| dip_float | upperBound | Upper bound of the uniform distribution the variable is | |
| | | drawn from | |
| dip_float* | output | output | |

EXAMPLE

Get a uniform random variable as follows:

```
dip_Random random;
dip_float lower, upper, value;

lower = -1.0;
upper = 1.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_UniformRandomVariable( &random, lower, upper, &value ));
```

DIPlib function reference

Unregister

761

Remove a registry item

SYNOPSIS

```
#include "dip_registry.h"
dip_Error dip_Unregister ( id, class )
```

FUNCTION

This function removes the Registry information of the ID of the Registry class class. See Register for more information about DIPlib's Registry.

ARGUMENTS

| Data type | Name | Description |
|--------------------------------|-------|----------------|
| $\mathtt{dip}_{-}\mathtt{int}$ | id | Registry ID |
| dip_int | class | Registry class |

SEE ALSO

 ${\tt Register}, {\tt RegistryList}, {\tt RegistryGet}, {\tt RegistryArrayNew}$

UpperEnvelope

Upper envelope transform (a flooding and an algebraic closing)

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_UpperEnvelope ( in, out, bottom, labels, connectivity,
max_depth, max_size )
```

DATA TYPES

integer, float

FUNCTION

The Upper envelope transform produces a flooding of the input image (which is an algebraic closing). See any article by F. Meyer for further explanations.

The Upper envelope is based on the watershed transform, each region being filled up to the level where it meets a neighbouring region. See Watershed for information on the parameters.

The bottom image is a second output image that contains the whole watershed region painted with the lowest value in it. It is useful for stretching the input image: (out - in) / (in - bottom). labels returns the label image used during region growing.

ARGUMENTS

| Data type | Name | Description |
|--------------------|--------------|--|
| ${\tt dip_Image}$ | in | Input |
| ${\tt dip_Image}$ | out | Output |
| dip_Image | bottom | Optional output |
| dip_Image | labels | Optional output |
| dip_int | connectivity | Connectivity |
| dip_float | max_depth | Maximum depth of a region that can be merged |
| dip_int | max_size | Maximum size of a region that can be merged |

SEE ALSO

Watershed, LocalMinima

Variance

statistics function

SYNOPSIS

dip_Error dip_Variance (in, mask, out, ps)

DATA TYPES

binary, integer, float

FUNCTION

Calculates the variance of the pixel values over all those dimensions which are specified by ps.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|----------|-----------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| $\mathtt{dip}_{-}\mathtt{Image}$ | mask (0) | Mask |
| dip_Image | out | Output |
| dip_BooleanArray | ps (0) | Dimensions to project |

VarianceFilter

Sample Variance Filter

SYNOPSIS

```
#include "dip_filtering.h"
dip_Error dip_VarianceFilter ( in, out, se, boundary, param, shape )
```

DATA TYPES

binary, **integer**, **float**

FUNCTION

This function calculates for every pixel the sample variance of the pixels in the filter window (its size specified by param).

Only the rectangular, elliptic and diamond filter shapes are supported (DIP_FLT_SHAPE_RECTANGULAR, DIP_FLT_SHAPE_ELLIPTIC and DIP_FLT_SHAPE_DIAMOND). Other filter shapes can be implemented by setting shape to

DIP_FLT_SHAPE_STRUCTURING_ELEMENT, and passing a binary image in se. The "on" pixels define the shape of the filter window. Other values of shape are illegal.

If shape is not equal to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, se can be set to zero. When shape is set to DIP_FLT_SHAPE_STRUCTURING_ELEMENT, param is ignored, and can be set to zero.

ARGUMENTS

| Data type | Name | Description |
|-------------------|----------|-------------------------------|
| dip_Image | in | Input |
| dip_Image | out | Output |
| dip_Image | se | Custom filter window (binary) |
| dip_BoundaryArray | boundary | Boundary conditions |
| dip_FloatArray | param | Filter sizes |
| dip_FilterShape | shape | Filter shape |

The enumerator dip_FilterShape contains the following constants:

| Name | Description |
|-----------------------------------|--|
| DIP_FLT_SHAPE_DEFAULT | Default filter window, same as |
| | DIP_FLT_SHAPE_RECTANGULAR |
| DIP_FLT_SHAPE_RECTANGULAR | Rectangular filter window, can be even in size |
| DIP_FLT_SHAPE_ELLIPTIC | Elliptic filter window, always odd in size |
| DIP_FLT_SHAPE_DIAMOND | Diamond-shaped filter window, always odd in |
| | size |
| DIP_FLT_SHAPE_PARABOLIC | Parabolic filter window (morphology only) |
| DIP_FLT_SHAPE_DISCRETE_LINE | Rotated line structuring element (morphology |
| | only) |
| DIP_FLT_SHAPE_INTERPOLATED_LINE | Rotated line structuring element, through |
| | interpolation (morphology only) |
| DIP_FLT_SHAPE_PERIODIC_LINE | (not implemented) |
| DIP_FLT_SHAPE_STRUCTURING_ELEMENT | Use se as filter window, can be any size |

VectorDistanceTransform

Euclidean vector distance transform

SYNOPSIS

```
#include "dip_distance.h"
dip_Error dip_VectorDistanceTransform ( in, outx, outy, outz, distance, border, method )
```

DATA TYPES

binary

FUNCTION

This function produces the vector components of the Euclidean distance transform. These are stored in the output images, one for each dimension of the input image. See the EuclideanDistanceTransform for detailed information about the parameters.

To compute the Euclidean distance from the vector components produced by this function, one needs to multiply each component with the sampling distance, square the result, sum the results for all components and take the square root of the sum.

ARGUMENTS

| Data type | Name | Description |
|---------------------------|----------|--------------------|
| ${\tt dip_Image}$ | in | Input image |
| $	exttt{dip_ImageArray}$ | out | Output images |
| dip_FloatArray | distance | Sampling distances |
| dip_Boolean | border | Image border type |
| dipf_DistanceTransform | method | Transform method |

dipf_DistanceTransform defines the following distance transform types:

| Name | Description |
|---------------------|---|
| DIP_EDT_FAST | fastest, but most errors |
| DIP_EDT_TIES | slower, but fewer errors |
| DIP_EDT_TRUE | slow, uses lots of memory, but is "error free" |
| DIP_EDT_BRUTE_FORCE | gives a result from which errors are calculated for the other |
| | methods. This method is extremly slow and should only be used |
| | for testing purposes. |

VoidPointerArrayCopy

Copy an array

SYNOPSIS

dip_Error dip_VoidPointerArrayCopy (dest, src, resources)

FUNCTION

This function copies the void pointer array src to dest. The array dest is created by this function as well.

ARGUMENTS

| Data type | Name | Description |
|--------------------|-----------|--|
| dip_IntegerArray * | dest | Destination array |
| dip_IntegerArray | src | Source array |
| dip_Resources | resources | Resources tracking structure. See ResourcesNew |

VoidPointerArrayFind

Find value in array

SYNOPSIS

dip_Error dip_VoidPointerArrayFind (array, value, index, found)

FUNCTION

Finds a value in an array and "returns" its index in the array. If found is zero, VoidPointerArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP_FALSE if value is not found).

ARGUMENTS

| Data type | Name | Description |
|----------------------|-------|--------------------------|
| dip_VoidPointerArray | array | Array to find value in |
| void * | value | Value to find |
| dip_int * | index | Index of the found value |
| dip_VoidPointer * | found | Value found or not |

VoidPointerArrayNew

Array allocation function

771

SYNOPSIS

dip_Error dip_VoidPointerArrayNew (array, size, resources)

FUNCTION

This function allocates the size elements of a dip_VoidPointerArrayNew and sets the size of the array to size.

ARGUMENTS

| Data type | Name | Description |
|------------------------|-----------|-----------------------------------|
| dip_VoidPointerArray * | array | Array |
| dip_int | size | Size |
| dip_Resources | resources | Resources tracking structure. See |
| | | ResourcesNew |

Watershed

Morphological segmentation

SYNOPSIS

```
#include "dip_morphology.h"
dip_Error dip_Watershed ( in, mask, out, connectivity, max_depth, max_size,
binaryOutput )
```

DATA TYPES

integer, float

FUNCTION

Watershed segmentation with built-in region merging. max_depth and max_size control the merging procedure. Any region with max_size or less pixels and with max_depth grey-value difference or less will be merged to neighbouring regions when they touch (as opposed to build a watershed). max_size equal to 0 means that the size of the region is not tested when merging. The regions are grown according to the connectivity parameter. See The connectivity parameter for more information. The output is either a labelled image where the pixels belonging to a catchment basin are labelled, or a binary image where the watershed pixels are 1 and the rest is 0. This is controlled by binaryOutput.

If mask is not 0, only the pixels within mask will be considered. All the other pixels will be marked as watershed pixels.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|--------------|--|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input |
| dip_Image | mask | Mask |
| dip_Image | out | Output |
| $\mathtt{dip}_{-}\mathtt{int}$ | connectivity | Connectivity |
| dip_float | max_depth | Maximum depth of a region that can be merged |
| dip_int | max_size | Maximum size of a region that can be merged |
| dip_Boolean | binaryOutput | DIP_FALSE if the output should be a labelled image |

Wiener

Image Restoration Filter

SYNOPSIS

```
#include "dip_restoration.h"
dip_Error dip_Wiener ( in, psf, signalPower, noisePower, out, flags )
```

FUNCTION

This function performs an image restoration using the Wiener filter. The Wiener filter is the linear restoration filter that is optimal in mean square error sense.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|-------------|-----------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in | Input image |
| $dip_{-}Image$ | psf | Point spread function image |
| dip_Image | signalPower | SignalPower image |
| dip_Image | noisePower | NoisePower image |
| dip_Image | out | Output image |
| dipf_Restoration | flags | Restoration flags |

Wrap

Wrap an image

SYNOPSIS

```
#include "dip_manipulation.h"
dip_Error dip_Wrap ( in, out, wrap )
```

DATA TYPES

binary, integer, float, complex

FUNCTION

This function wraps the in image around its image borders. wrap specifies the number of pixels over which the image has to wrapped in each dimension.

ARGUMENTS

| Data type | Name | Description |
|---|------|----------------|
| ${\tt dip_Image}$ | in | Input image |
| ${\tt dip_Image}$ | out | Output image |
| $\mathtt{dip}_{-}\mathtt{IntegerArray}$ | wrap | Wrap parametrs |

Xor

logic operation

SYNOPSIS

dip_Error dip_Xor (in1, in2, out)

DATA TYPES

binary, integer

FUNCTION

The function Xor performs the logic XOR operation between the corresponding pixels in in1 and in2, and stores the result in out.

ARGUMENTS

| Data type | Name | Description |
|----------------------------------|------|---------------------------|
| $\mathtt{dip}_{-}\mathtt{Image}$ | in1 | First binary input image |
| $\mathtt{dip}_{-}\mathtt{Image}$ | in2 | Second binary input image |
| dip_Image | out | Output image |

SEE ALSO

Chapter 3

Assorted topics

3.1 Boundary conditions

Neighbourhood operations pose a problem. What happens when the neighbourhood operator operates near the border of the image and needs data from the area outside the image? The usual solution, also adopted by DIPlib, is to silently extend the image. There are various ways of extending the boundary. Below is a list of the possible methods. More details can be found in the user guide. Note that not all functions support all of these.

| Name | Description | |
|----------------------|------------------------------------|--|
| DIP_BC_SYM_MIRROR | Symmetric mirroring | |
| DIP_BC_ASYM_MIRROR | Asymmetric mirroring | |
| DIP_BC_PERIODIC | Periodic copying | |
| DIP_BC_ASYM_PERIODIC | Asymmetric periodic copying | |
| DIP_BC_ADD_ZEROS | Extending the image with zeros | |
| DIP_BC_ADD_MAX_VALUE | Extending the image with +infinity | |
| DIP_BC_ADD_MIN_VALUE | Extending the image with -infinity | |

SEE ALSO

BoundaryArrayNew, BoundaryArrayFree FillBoundaryArray, SeparableFrameWork

3.2 Compression methods for image files

The dipio_Compression structure

The structure dipio_Compression specifies the compression method to use when writing an image file, and contains the following elements:

| Data type | Name | Description |
|-------------------------|--------|--|
| dipio_CompressionMethod | method | Compression method |
| dip_int | level | Compression parameter, dependent on method |

dipio_CompressionMethod is an enum with the known compression methods. File formats typically only support one or a few of these, and most of these methods do not have a parameter to set, in which case level is ignored. If an unsupported compression method is selected, no compression is done. The dipio_CompressionMethod has the following values:

| Name | Description |
|---|---|
| DIPIO_CMP_DEFAULT | Default compression method for the file format |
| DIPIO_CMP_NONE | No compression |
| DIPIO_CMP_GZIP | ZIP compression, using zlib. The level parameter is between |
| | 1 and 10, 1 being the faster, lesser compression and 10 being |
| | the slower, higher compression. |
| DIPIO_CMP_DEFLATE | Deflate (same as DIPIO_CMP_GZIP) |
| DIPIO_CMP_COMPRESS | Using UNIX's "compress" utility, which uses the LZW |
| | algorithm |
| DIPIO_CMP_LZW | LZW compression (same as DIPIO_CMP_COMPRESS) |
| DIPIO_CMP_JPEG | Lossy JPEG compression. The level parameter is between 1 |
| | and 100, higher numbers giving better quality output but |
| | larger files. |
| DIPIO_CMP_PACKBITS | PackBits |
| DIPIO_CMP_THUNDERSCAN | ThunderScan |
| DIPIO_CMP_NEXT | NeXT |
| DIPIO_CMP_CCITTRLE | CCITT RLE |
| DIPIO_CMP_CCITTRLEW | CCITT RLE/W |
| DIPIO_CMP_CCITTFAX3 | CCITT Group 3 |
| DIPIO_CMP_CCITTFAX4 | CCITT Group 4 |
| DIPIO_CMP_NEXT DIPIO_CMP_CCITTRLE DIPIO_CMP_CCITTRLEW DIPIO_CMP_CCITTFAX3 | NeXT CCITT RLE CCITT RLE/W CCITT Group 3 |

Thus only DIPIO_CMP_GZIP and DIPIO_CMP_JPEG currently have a level to set.

Supported compression methods for the various file formats

The TIFF file writer understand the methods DIPIO_CMP_NONE, DIPIO_CMP_DEFLATE, DIPIO_CMP_LZW, DIPIO_CMP_JPEG, DIPIO_CMP_PACKBITS, DIPIO_CMP_THUNDERSCAN, DIPIO_CMP_NEXT, DIPIO_CMP_CCITTRLE, DIPIO_CMP_CCITTRLEW, DIPIO_CMP_CCITTFAX3 and DIPIO_CMP_CCITTFAX4. It defaults to DIPIO_CMP_DEFLATE. The level parameter is currently not used.

The ICS file writer understands DIPIO_CMP_NONE, DIPIO_CMP_GZIP and DIPIO_CMP_COMPRESS, although DIPIO_CMP_COMPRESS is currently not implemented. It defaults to DIPIO_CMP_GZIP.

The GIF file writer only understands <code>DIPIO_CMP_LZW</code>. The compression method selected is simply ignored.

The JPEG file writer only understands <code>DIPIO_CMP_JPEG</code>. The compression method selected is simply ignored.

All other file writers do not compress, and simply ignore the compression method requested.

3.3 DerivativeSpec data structure

STRUCTURE

This structure is an aggregate of common parameters for derivative operators. Its current definition is:

```
typedef struct
{
    dip_DerivativeFlavour flavour;
    dip_float truncation;
} dip_DerivativeSpec;
```

The enumerator flavour parameter is one of:

| Name | Description |
|-------------------|--|
| DIP_DF_DEFAULT | Default derivative flavour (==DIP_DF_FIRGAUSS) |
| DIP_DF_FIRGAUSS | Gaussian family, FIR implementation, Gauss |
| DIP_DF_IIRGAUSS | Gaussian family, IIR implementation, GaussIIR |
| DIP_DF_FTGAUSS | Gaussian family, FT implementation, GaussFT |
| DIP_DF_FINITEDIFF | Finite difference implementation, FiniteDifferenceEx |

SEE ALSO

StructureTensor2D, Derivative

3.4 DIPlib's data types

| Pixel values are represented by different ty | pes, called data types. | DIPlib supports the data |
|--|-------------------------|--------------------------|
| types given in the following table: | | |

| data type | dip_DataType | data type | suffix |
|--------------|-----------------|-------------------|--------|
| | | identifier | |
| dip_bin8 | DIP_DT_BIN8 | DIP_DTID_BIN8 | _b8 |
| dip_bin16 | DIP_DT_BIN16 | DIP_DTID_BIN16 | _b16 |
| dip_bin32 | DIP_DT_BIN32 | DIP_DTID_BIN32 | _b32 |
| dip_uint8 | DIP_DT_UINT8 | DIP_DTID_UINT8 | _u8 |
| dip_uint16 | DIP_DT_UINT16 | DIP_DTID_UINT16 | _u16 |
| dip_uint32 | DIP_DT_UINT32 | DIP_DTID_UINT32 | _u32 |
| dip_sint8 | DIP_DT_SINT8 | DIP_DTID_SINT8 | _s8 |
| dip_sint16 | DIP_DT_SINT16 | DIP_DTID_SINT16 | _s16 |
| dip_sint32 | DIP_DT_SINT32 | DIP_DTID_SINT32 | _s32 |
| dip_sfloat | DIP_DT_SFLOAT | DIP_DTID_SFLOAT | _sfl |
| dip_dfloat | DIP_DT_DFLOAT | DIP_DTID_DFLOAT | _dfl |
| dip_scomplex | DIP_DT_SCOMPLEX | DIP_DTID_SCOMPLEX | _SCX |
| dip_dcomplex | DIP_DT_DCOMPLEX | DIP_DTID_DCOMPLEX | _dcx |

The data types can be divided into five classes: the binary, unsigned integer, signed integer, floating point and complex classes. Different data types in the same class (e.g. dip_uint8 and dip_uint16) provide a different range of values they can represent.

The complex data types are defines as follows:

```
typedef struct
{
    dip_sfloat re;
    dip_sfloat im;
} dip_scomplex;

typedef struct
{
    dip_dfloat re;
    dip_dfloat im;
} dip_dcomplex;
```

The binary data types are simply aliases for a set of corresponding unsigned integer types. The reason for having a separate typedef for the binary types is that they are not used like ordinary integers. Each bit of the integer can store one binary value. When manipulating binary data, care must be taken not to change any of the other bits of the integer used for storing it.

The dip_DataType enumeration is used to represent data types symbolically. It is used in dip_Image's to indicate what the data type of the image is. Data type identifiers are used by the type iterator (see tpi.h) and overload schemes (see ovl.h and overload.h). Type suffixes are used to give type specific routines a unique name. Using a standard set of suffixes enables the type iterator and overload schemes to deal with these type specific routines. The dip_DataType enumeration, data type identifiers and suffixes can be found in the table above.

In addition to the data type identifiers for individual data types, there are also defines to represent an entire group. These are given in the following table:

| Data type identifier group | data types |
|----------------------------|--|
| DIP_DTGID_UINT | unsigned integer |
| DIP_DTGID_UNSIGNED | unsigned integer |
| DIP_DTGID_SINT | signed integer |
| DIP_DTGID_INT | signed and unsigned integer |
| DIP_DTGID_INTEGER | signed and unsigned intege |
| DIP_DTGID_FLOAT | floating-point |
| DIP_DTGID_REAL | integer and floating-point |
| DIP_DTGID_COMPLEX | complex floating-point |
| DIP_DTGID_SIGNED | signed integer, floating-point and complex |
| DIP_DTGID_BINARY | binary |
| DIP_DTGID_ALL | all |

DataTypeGetInfo

3.5 Description of DIPlib's pixel tables

Pixel tables provide an efficient way to encode a multi-dimensional binary object. DIPlib's dip_PixelTable implements this using runlength encoding (in 2-D this coding scheme is known as pxy-tables).

A DIPlib pixel table is a structure (defined in dip_pixel_table.h) that incorporates a link-list of runlengths. Each run-length consists of a n-D coordinate (integer array) and the length of the run along the X dimension. All the runlengths in total encode the binary object.

LITERATURE

See section 3.6, "Contour representations", in Fundamentals of Image Processing.

I.T. Young, R.L. Peverini, P.W. Verbeek and P.J. van Otterloo, A New Implementation for Binary and Minkowski Operators, Computer Graphics and Image Processing, Volume 17, No. 3, 189-210, 1981

3.6 File formats recognized by dipIO

The Registry

A number of file reading and writing functions are included in dipIO. These are registered in the ImageReadRegistry and the ImageWriteRegistry. Through this registry, ImageRead and ImageWrite are able to read from and write to any registered file format. You can add your own functions to these (the interface functions for this are not documented yet), thereby increasing the possibilities of ImageRead and ImageWrite.

Below you can find a list of currently supported file formats for both reading and writing. To obtain the format ID from the registry, you need to include the specified file and call the specified function.

Reading

These are the file formats currently supported for reading:

789

| format | include file | registry ID | dimension- | colour | data types |
|-------------|--------------|-----------------------|------------|--------|---------------|
| | | retrieval | ality | | |
| | | function | | | |
| ICS (Image | | | any | yes | any |
| Cytometry | dipio_ics.h | dipio_ReadIC | SID | | |
| Standard) | | | | | |
| TIFF | | | 2D | yes | any |
| (Tagged | dipio_tiff.h | dipio_ReadTI | FFID | | |
| Image File | | | | | |
| Format) | | | | | |
| JPEG | | | 2D | yes | uint8 |
| (JPEG File | dipio_jpeg.h | dipio_ReadJP | EGID | | |
| Interchange | | | | | |
| Format) | | | | | |
| GIF | | | 2D | yes | uint8 |
| (Graphics | dipio_gif.h | ${\tt dipio_ReadGI}$ | FID | | |
| Interchange | | | | | |
| Format) | | | | | |
| LSM (Zeiss | | | 1D - 4D | no | uint8, uint16 |
| LSM file | dipio_lsm.h | dipio_ReadLS | MID | | and sfloat |
| format) | | | | | |
| PIC | | | 2D and 3D | no | uint8 |
| (BioRad | dipio_pic.h | dipio_ReadPI | CID | | |
| PIC file | | | | | |
| format) | | | | | |
| CVS | | | 2D | no | sfloat |
| (Comma | dipio_csv.h | dipio_ReadCS | VID | | |
| Separated | | | | | |
| Values) | | | | | |

${\sf Writing}$

These are the file formats currently supported for writing:

| format | include file | registry ID retrieval function | dimension- ality | colour | data types |
|--|--------------|--------------------------------------|---------------------|--------|--|
| ICS v1 (Image Cytometry Standard) | dipio_ics.h | dipio_WriteI | any CSv1ID | yes | any, binXX converted to uintXX |
| ICS v2 (Image Cytometry Standard) | dipio_ics.h | dipio_WriteI | any CSv2ID | yes | any, binXX converted to uintXX |
| TIFF (Tagged Image File Format) | dipio_tiff.h | dipio_WriteT | 2D IFFID | yes | any in grey-value, uint8 in colour |
| JPEG (JPEG File Interchange Format) | dipio_jpeg.h | dipio_WriteJ | 2D PEGID | yes | uint8 |
| GIF (Graphics Interchange Format) | dipio_gif.h | dipio_WriteG | 2D IFID | no | uint8 |

3.7 From images to scalars

Within DIPlib all data, i.e. multi-dimensional data, such as images, and scalar, are all represented by the same object: the image. Scalars are stored as zero dimensional images. Examine, for example, the following code to compute the sum over all the grey values:

```
dip_Image img;
dip_Image value;
...
dip_Sum ( img, 0, value, 0 );
```

Which stores the sum over all the pixel values of img in the 0-D image value. We often want to directly manipulate scalars, in which case we need to extract the value. This can be accomplished easily with the GetInteger, GetFloat or the GetComplex functions:

```
dip_Image img;
dip_Image valueimg;
dip_float value;
...
dip_Sum ( img, 0, valueimg, 0 );
dip_GetFloat ( valueimg, &value, 0 );
printf ( "The sum is: %f\n", value );
```

3.8 General information about convolution

Convolution can be explained in just a few words: it is a local weighted average (the weights can be negative). This of course does not explain how to use it or what its properties are. For this we refer to the following sources:

Ian T. Young, Jan J. Gerbrands and Lucas J. van Vliet, Fundamentals of Image Processing. Alan V. Oppenheim, Alan S. Willsky and I.T. Young, "Signals and Systems", Prentice-Hall, 1983.

Anil K. Jain, "Fundamentals of Digital Image Processing", Prentice-Hall, 1989.

"The Digital Signal Processing Handbook", Vijay K. Madisetti and Douglas B. Williams (eds), CRC Press + IEEE Press, 1998.

Kenneth R. Castleman, "Digital Image Processing", Prentice-Hall, 1996.

3.9 General information about sorting

There are two kinds of sorting routines in DIPlib. The first sorts a one-dimensional array of data, the second sorts a set of indices to a one-dimensional array of data. The result of the sort routines can be summarised as follows:

```
Sort: data[ i ] <= data[ i + 1 ]
Sort indices: data[ indices[ i ] ] <= data[ indices[ i + 1 ] ]</pre>
```

Note that the number of indices does not have to be equal to the amount of pixels in the image, it may be either smaller or larger. The indices themselves should of course "point" to a valid pixel.

The sorting algorithms are described in the following reference:

Donald E. Knuth, "The Art of Computer Programming, volume 3: Sorting and Searching", second edition, Addison-Wesley, 1998.

3.10 Information about dyadic operations

There are two types of dyadic operations. First there are operations such as Add, Sub, etc... which take two input images. The second category consists of functions such as AddFloat, AddComplex etc... The data type of the output image given the data types of the input images is given by the following table:

| | dcomplex | scomplex | dfloat | sfloat | sint32 | sint16 |
|----------|----------|----------|----------|----------|----------|----------|
| dcomplex |
| scomplex | dcomplex | scomplex | dcomplex | scomplex | scomplex | scomplex |
| dfloat | dcomplex | dcomplex | dfloat | dfloat | dfloat | dfloat |
| sfloat | dcomplex | scomplex | dfloat | sfloat | sfloat | sfloat |
| sint32 | dcomplex | scomplex | dfloat | sfloat | sint32 | sint32 |
| sint16 | dcomplex | scomplex | dfloat | sfloat | sint32 | sint16 |
| sint8 | dcomplex | scomplex | dfloat | sfloat | sint32 | sint16 |
| uint32 | dcomplex | scomplex | dfloat | sfloat | sint32 | sint32 |
| uint16 | dcomplex | scomplex | dfloat | sfloat | sint32 | sint16 |
| uint8 | dcomplex | scomplex | dfloat | sfloat | sint32 | sint16 |
| binary | dcomplex | scomplex | dfloat | sfloat | sint32 | sint16 |
| | sint8 | uint32 | uint16 | uint8 | binary | |
| dcomplex | dcomplex | dcomplex | dcomplex | dcomplex | dcomplex | |
| scomplex | scomplex | scomplex | scomplex | scomplex | scomplex | |
| dfloat | dfloat | dfloat | dfloat | dfloat | dfloat | |
| sfloat | sfloat | sfloat | sfloat | sfloat | sfloat | |
| sint32 | sint32 | sint32 | sint32 | sint32 | sint32 | |
| sint16 | sint16 | sint32 | sint16 | sint16 | sint16 | |
| sint8 | sint8 | sint32 | sint16 | sint8 | sint8 | |
| uint32 | sint32 | uint32 | uint32 | uint32 | uint32 | |
| uint16 | sint16 | uint32 | uint16 | uint16 | uint16 | |
| uint8 | sint8 | uint32 | uint16 | uint8 | uint8 | |
| binary | sint8 | uint32 | uint16 | uint8 | sint8 | |

The output data type of an operation involving an image and a constant of one of the types: dip_complex, dip_float, dip_int, is given by the following table:

| | dip_complex | dip_float | dip_int |
|----------|-------------|-----------|----------|
| dcomplex | dcomplex | dcomplex | dcomplex |
| scomplex | scomplex | scomplex | scomplex |
| dfloat | dcomplex | dfloat | dfloat |
| sfloat | scomplex | sfloat | sfloat |
| sint32 | scomplex | sint32 | sint32 |
| sint16 | scomplex | sint16 | sint16 |
| sint8 | scomplex | sint8 | sint8 |
| uint32 | scomplex | uint32 | uint32 |
| uint16 | scomplex | uint16 | uint16 |
| uint8 | scomplex | uint8 | uint8 |
| binary | scomplex | sint8 | sint8 |

3.11 The image structure

DESCRIPTION

dip_Image is the structure that is used to store images in DIPlib. It contains a number of fields that are used to describe an image. The type field stores the type of the image using a dip_ImageType enumeration. Currently scalar images are the only supported type (DIP_IMTP_SCALAR). The DIP_IMTP_ALIEN type is used internally by DIPlib for creating interfaces to other packages. Whether the other fields in the dip_Image are meaningful depends on the image type. A dip_Image may contain fields specific to the current image type. These will be discussed on the pages pertaining to the type in question. The standard fields that are always present are:

| field type | short description | access functions |
|------------------------------|---------------------------|------------------------------|
| $	extstyle{dip_ImageType}$ | The image type | ImageGetType, |
| | | ImageSetType |
| $	extstyle{dip_ImageState}$ | The image state | (none) |
| dip_DataType | Data type used to store | <pre>ImageGetDataType,</pre> |
| | pixel values | ImageSetDataType |
| $	exttt{dip_IntegerArray}$ | Dimensions of the image | ImageGetDimensions, |
| | | ImageGetDimensionality, |
| | | ImageSetDimensions |
| void * | Pointer to the pixel data | ImageGetData |
| dip_int | Plane number, for binary | ImageGetPlane |
| | images | |
| $	exttt{dip_IntegerArray}$ | Stride array (see below) | ImageGetStride |

Pixel values are stored in the data type specified by the data type field. For a list of possible data types see DIPlib's data types.

The dimensionality of the image and the size of each individual dimension is stored in the dimensions Array.

The data pointer points to the pixel at the origin of the image. For each dimension the stride array holds the interleave between two neighbouring pixels in memory. The following equation may be used to compute the address of a pixel at a coordinate specified by an array called <code>cor[]</code>:

A dip_Image structure does not necessarily have pixel data associated with it. When a dip_Image does not contain pixel data, it is said to be in the "raw" state. A dip_Image that does contain data, is said to be "forged". For binary images the plane field holds the number of the bit in which the binary data is stored. Access to the fields of a dip_Image is

DIP*lib* function reference 797

restricted to a number of functions, which are given in the table above. The "set" functions can only be used on "raw" images.

3.12 The connectivity parameter

DIPlib uses a different name for the various possible connectivites than you might be used to. This is to generalize this parameter to images of any dimensionality. It is defined as follows: if connectivity is 1 all pixels for which only one coordinate differs from the pixel's coordinates by maximally 1 are considered neighbours; if it is 2, all pixels for which one or two coordinates differ maximally 1 are considered neighbours. The connectivity can never be larger than the image dimensionality.

In terms of the obsolete connectivity definitions we have:

| In 2-D | this connectivity | corresponds to | and forms this |
|--------|-------------------|-------------------|--------------------|
| | | | structuring |
| | | | element |
| | 1 | 4 connectivity | diamond |
| | 2 | 8 connectivity | square |
| | -1 | 4-8 connectivity | octagon |
| | -2 | 8-4 connectivity | octagon |
| In 3-D | this connectivity | corresponds to | and forms this |
| | | | structuring |
| | | | element |
| | 1 | 6 connectivity | octahedron |
| | 2 | 18 connectivity | cuboctahedron |
| | 3 | 26 connectivity | cube |
| | -1 | 6-26 connectivity | small rhombicuboc- |
| | | | tahedron |
| | -3 | 26-6 connectivity | small rhombicuboc- |
| | | | tahedron |

The negative connectivities are only defined for the functions in binary morphology such as <code>BinaryDilation</code> and <code>BinaryErosion</code>. These alternate steps with different connectivity to produce a better approximation to an isotropic structuring element.
