Chapter 1

Indices of functions by subject

# 1.1 Library Functions

# 1.1.1 Image Object

- ChangeDataType Change the data type of an image
- ChangeDimensions Changes the order of the dimensions in an image
- ChangeToOd Make an image zero dimensional
- HasNormalStride Determines whether an image has a normal stride
- ImageAssimilate Inherit properties of another image
- ImageCopyProperties Copy the properties of an image
- ImageForge Allocate pixel data for an image
- ImageFree Free an image
- ImageGetData Get the data pointers of a set of images
- ImageGetDataType Read the data type field
- ImageGetDimensionality Read the dimensionality field
- ImageGetDimensions Read the dimensions array
- ImageGetPlane Read the plane number
- ImageGetStride Read the stride array
- ImageGetType Read the type field
- ImageNew Allocate a structure
- ImagesCheck Check properties of several images
- ImagesCheckTwo Check properties of two images
- ImagesCompare Compare properties of several images
- ImagesCompareTwo Compare properties of two images
- ImageSetDataType Set the data type field
- ImageSetDimensions Set the dimensions array
- ImageSetType Set the image type field
- ImagesSeparate Take care of in-place operations
- ImageStrip Restore an image to its initial ("raw") state

# 1.1.2 Scalar Images

- ConvertDataType Converts the data type of an image
- IsScalar Determines whether an image is a scalar
- ScalarImageNew Allocate a scalar image

# 1.1.3 Strings

- StringAppend Append a string to another
- StringArrayCopy Copy a string array
- StringArrayFree Array free function
- StringArrayNew Allocate an array of strings
- StringCat Concatenate two strings
- StringCompare Compare two strings
- StringCompareCaseInsensitive Compare two strings without minding case
- StringCopy Copy a String
- StringCrop Crop a string
- StringFree Free a string
- StringNew Allocate a string
- StringReplace Replace the contents of one string with that of another
- UnderscoreSpaces Replace spaces with underscores

# 1.1.4 Arrays

- ArrayFree Array free function
- ArrayNew Array allocation function
- BooleanArrayCopy Copy an array
- BooleanArrayFind Find value in array
- BooleanArrayFree Array free function
- BooleanArrayNew Array allocation function
- BoundaryArrayFree Array free function
- BoundaryArrayNew Array allocation function

- ComplexArrayCopy Copy an array
- ComplexArrayFind Find value in array
- ComplexArrayFree Array free function
- ComplexArrayNew Array allocation function
- ConvertArray converts the data type of an array
- CoordinateArrayFree Array free function
- CoordinateArrayNew Array allocation function
- DataTypeArrayCopy Copy an array
- DataTypeArrayFind Find value in array
- DataTypeArrayFree Array free function
- DataTypeArrayNew Array allocation function
- FloatArrayCopy Copy an array
- FloatArrayFind Find value in array
- FloatArrayFree Array free function
- FloatArrayNew Array allocation function
- FrameWorkProcessArrayFree Array free function
- FrameWorkProcessArrayNew Array allocation function
- ImageArrayFree Array free function
- ImageArrayNew Array allocation function
- ImageCheckBooleanArray Check a boolean array
- ImageCheckComplexArray Check a complex array
- ImageCheckFloatArray Check a float array
- ImageCheckIntegerArray Check an integer array
- IntegerArrayCopy Copy an array
- IntegerArrayFind Find value in array
- IntegerArrayFree Array free function
- IntegerArrayNew Array allocation function
- StringArrayCopy Copy a string array

- StringArrayFree Array free function
- StringArrayNew Allocate an array of strings
- VoidPointerArrayCopy Copy an array
- VoidPointerArrayFind Find value in array
- VoidPointerArrayFree Array free function
- VoidPointerArrayNew Array allocation function

#### 1.1.5 Frameworks

- MonadicFrameWork FrameWork for monadic operations
- PixelTableFrameWork FrameWork for PixelTable filters
- ScanFrameWork FrameWork for scanning multiple images
- SeparableFrameWork FrameWork for separable filters
- SingleOutputFrameWork FrameWork for generation functions

#### 1.1.6 Pixel Tables

- BinaryImageToPixelTable Convert a binary image to a pixel table
- PixelTableAddRun Add a new run to a pixel table
- PixelTableCreateFilter Create a pixel table from a filter shape
- PixelTableFrameWork FrameWork for PixelTable filters
- PixelTableGetDimensionality Get the dimensionality of a pixel table
- PixelTableGetDimensions Get the dimensions of a pixel table
- PixelTableGetOffsetAndLength Converts the pixel table's runs
- PixelTableGetOrigin Get the origin of the pixel table
- PixelTableGetPixelCount Get the number of pixels encoded in the pixel table
- PixelTableGetRun Get the contents of a pixel table run
- PixelTableGetRuns Get the number of runs in a pixel table
- PixelTableGetSize The number of pixels in the pixel table's bounding box
- PixelTableNew Allocate a new pixel table
- PixelTableSetRun Initialises a pixel table run
- PixelTableToBinaryImage Convert a pixel table to a binary image

# 1.1.7 Data Structures

- PixelHeapFree Destroy heap structure
- PixelHeapIsEmpty Query heap
- PixelHeapNew Create a new heap structure
- PixelHeapPop Pop item onto heap
- PixelHeapPush Push item onto heap
- PixelQueueFree Destroy queue structure
- PixelQueueIsEmpty Query queue
- PixelQueueNew Create a new queue structure
- PixelQueuePop Pop item from queue
- PixelQueuePush Push item onto queue
- StablePixelHeapFree Destroy heap structure
- StablePixelHeapIsEmpty Query heap
- StablePixelHeapNew Create a new heap structure
- StablePixelHeapPop Pop item onto heap
- StablePixelHeapPush Push item onto heap

# 1.1.8 Numerical Algorithms

• OneDimensionalSearch - Numerical algorithm

# 1.1.9 Sorting

- DistributionSort Sort a block of data
- DistributionSortIndices Sort indices to block of data
- DistributionSortIndices16 Sort indices to a block of data
- GetRank Value selection function
- ImageSort Sort image data
- ImageSortIndices Sort indices to image data
- InsertionSort Sort a block of data
- InsertionSortIndices Sort indices to a block of data

- InsertionSortIndices16 Sort indices to a block of data
- QuickSort Sort a block of data
- QuickSortAnything Sort data of any type
- QuickSortIndices Sort indices to a block of data
- QuickSortIndices16 Sort indices to a block of data
- Sort Sort a block of data
- SortAnything Sort data of any type
- SortCompareFunction Typedef for comparison function (sorting)
- SortIndices Sort indices to a block of data
- SortIndices16 Sort indices to a block of data
- SortSwapFunction Typedef for swap and copy function (sorting)

# 1.1.10 Indexing

- CoordinateToIndex Convert coordinate to pixel index
- dip\_PixelGetFloat Midlevel PixelIO function
- dip\_PixelGetInteger Midlevel PixelIO function
- dip\_PixelSetFloat Midlevel PixelIO function
- dip\_PixelSetInteger Midlevel PixelIO function
- Get Get a pixel value
- GetComplex Get complex pixel value
- GetFloat Get float pixel value
- GetInteger Get integer pixel value
- IndexToCoordinate Convert pixel index to coordinate
- IndexToCoordinateWithSingletons Convert pixel index to coordinate
- NeighbourIndicesListMake Get indices to direct neighbours
- NeighbourListMake Get list of direct neighbours
- NeighbourListMakeChamfer Get list of neighbours based on Chamfer metric
- NeighbourListMakeImage Get list of neighbours based on metric in image
- NeighbourListToIndices Get indices to neighbours

- Set the value of a pixel
- SetComplex Set a pixel value
- SetFloat Set a pixel value
- SetInteger Set a pixel value

## 1.1.11 Memory Management

- MemoryCopy Copy memory blocks
- MemoryFree Free a chunk of memory
- MemoryFunctionsSet Sets memory allocation functions
- MemoryNew Allocate and track memory
- MemoryReallocate Reallocate a chunk of memory
- ResourcesFree Free resources
- ResourcesMerge Add one resource list to another
- ResourcesNew Allocate a resource tracking structure
- ResourceSubscribe Track a resource
- ResourceUnsubscribe Stop tracking a resource

# 1.1.12 Support Functions

- DataTypeAllowed Check whether a data type is allowed
- DataTypeGetInfo Get information about a data type
- error.h Contains error messages
- ErrorFree Free a DIPlib call tree
- Exit Clean up before exiting
- FillBoundaryArray Fill the border of array according to the boundary condition
- GetLibraryInformation Support function
- GetUniqueNumber Obtain an unique value
- GlobalBoundaryConditionGet Get global Boundary Conditions
- GlobalBoundaryConditionSet Set global boundary conditions
- GlobalFilterShapeGet Get global filter shape value

- GlobalFilterShapeSet Set the global filter shape value
- GlobalGaussianTruncationGet Get the global gaussian truncation
- GlobalGaussianTruncationSet Set the global gaussian truncation
- Initialise Initialise DIPlib
- macros.h Various macros
- ovl.h Call an overloaded function
- Physical Dimensions Copy Copy a Physical Dimensions
- Physical Dimensions Free Free a Physical Dimensions data structure
- Physical Dimensions Is Isotropic Checks if the Physical Dimensions are isotropic
- Physical Dimensions New Allocates a new Physical Dimensions structure
- Register Generic registry function
- RegisterClass Register a registry class
- RegistryArrayNew Allocate a registry array
- RegistryGet Get a registry item
- RegistryList Get an array of registry IDs
- RegistryValid Validate an registry item
- TimerGet Timing functions
- TimerSet Timing functions
- tpi.h Type iterator
- Unregister Remove a registry item

# 1.2 File I/O functions

# 1.2.1 File IO

- Colour2Gray Convert ND image with colour information to a (n-1)D grayvalue image (in dipIO)
- ImageFileGetInfo Get information about image in file (in dipIO)
- ImageFileInformationFree Free a Image File Information structure (in dipIO)
- ImageFileInformationNew Allocate an Image File Information structure (in dipIO)
- ImageIsGIF Confirm that a file is a GIF file (in dipIO)

- ImageIsICS Confirm that a file is an ICS file (in dipIO)
- ImageIsJPEG Confirm that a file is a JPEG file (in dipIO)
- ImageIsLSM Confirm that a file is a Zeiss LSM file (in dipIO)
- ImageIsTIFF Confirm that a file is a TIFF file (in dipIO)
- ImageRead Read grey-value image from file (in dipIO)
- ImageReadColour Read colour image from file (in dipIO)
- ImageReadCSV Read comma-separated values from file (in dipIO)
- ImageReadCSVInfo Get information about image in comma-separated values file (in dipIO)
- ImageReadGIF Read a GIF image from file (in dipIO)
- ImageReadGIFInfo Get information about image in GIF file (in dipIO)
- ImageReadICS Read ICS image from file (in dipIO)
- ImageReadICSInfo Get information about image in ICS file (in dipIO)
- ImageReadJPEG Read JPEG image from file (in dipIO)
- ImageReadJPEGInfo Get information about image in JPEG file (in dipIO)
- ImageReadLSM Read Zeiss LSM image from file (in dipIO)
- ImageReadLSMInfo Get information about image in LSM file (in dipIO)
- ImageReadPIC Read BioRad PIC image from file (in dipIO)
- ImageReadPICInfo Get information about image in BioRad PIC file (in dipIO)
- ImageReadROI Read a portion of a grey-value image from file (in dipIO)
- ImageReadTIFF Read TIFF image from file (in dipIO)
- ImageReadTIFFInfo Get information about image in TIFF file (in dipIO)
- ImageWrite Write grey-value image to file (in dipIO)
- ImageWriteColour Write colour image to file (in dipIO)
- ImageWriteCSV Write image to a comma-separated-value file (in dipIO)
- ImageWriteEPS Write image to Encapsulated PostScript file (in dipIO)
- ImageWriteFLD Write image to AVS field file (in dipIO)
- ImageWriteGIF Write image to a GIF file (in dipIO)
- ImageWriteICS Write ICS image to file (in dipIO)

- ImageWriteJPEG Write JPEG image to file (in dipIO)
- ImageWritePS Write image to PostScript file (in dipIO)
- ImageWriteTIFF Write TIFF image to file (in dipIO)
- MeasurementRead Read measurement results from a file
- MeasurementWrite Write measurement results to a file
- MeasurementWriteCSV Write measurement results to a CSV file
- MeasurementWriteHTML Write measurement results to an HTML file
- MeasurementWriteText Write measurement results as readable text

# 1.3 Image Processing Functions

# 1.3.1 Mathematics

- Abs Arithmetic function
- Acos trigonometric function
- Add arithmetic function
- AddComplex arithmetic function
- AddFloat arithmetic function
- And logic operation
- Asin trigonometric function
- Atan trigonometric function
- Atan2 arithmetic function
- BesselJO mathematical function
- BesselJ1 mathematical function
- BesselJN mathematical function
- BesselYO mathematical function
- Bessel Y1 mathematical function
- BesselyN mathematical function
- Ceil Arithmetic function
- Compare Compare grey values in two images
- Cos trigonometric function

- Cosh trigonometric function
- CumulativeSum statistics function
- Div arithmetic function
- DivComplex arithmetic function
- DivFloat arithmetic function
- Equal Compare grey values in two images
- Erf mathematical function
- Erfc mathematical function
- $\bullet$  Exp arithmetic function
- Exp10 arithmetic function
- $\bullet$  Exp2 arithmetic function
- Floor Arithmetic function
- Fraction Arithmetic function
- GetMaximumAndMinimum statistics function
- Greater Compare grey values in two images
- IDivergence difference measure
- Imaginary Arithmetic function
- Invert logic operation
- Lesser Compare grey values in two images
- Ln arithmetic function
- LnGamma mathematical function
- LnNormError difference measure
- Log10 arithmetic function
- Log2 arithmetic function
- Max arithmetic function
- MaxFloat arithmetic function
- Maximum statistics function
- mBesselJO mathematical function
- mBesselJ1 mathematical function

- mBesselJN mathematical function
- mBesselYO mathematical function
- mBesselY1 mathematical function
- mBesselYN mathematical function
- Mean statistics function
- MeanAbsoluteError difference measure
- MeanError difference measure
- MeanModulus statistics function
- MeanSquareError difference measure
- MeanSquareModulus statistics function
- Median statistics function
- mErf mathematical function
- mErfc mathematical function
- mExp10 mathematical function
- mExp2 mathematical function
- mFraction mathematical function
- mGammaP mathematical function
- mGammaQ mathematical function
- Min arithmetic function
- MinFloat arithmetic function
- Minimum statistics function
- mLnGamma mathematical function
- mLog2 mathematical function
- mNearestInt mathematical function
- Modulo Arithmetic function
- Modulus Arithmetic function
- mReciprocal mathematical function
- mSign mathematical function
- mSinc mathematical function

- mTruncate mathematical function
- Mul arithmetic function
- MulComplex arithmetic function
- Mulfloat arithmetic function
- NearestInt Arithmetic function
- NormaliseSum Normalise the sum of the pixel values
- NotEqual Compare grey values in two images
- NotGreater Compare grey values in two images
- NotLesser Compare grey values in two images
- Or logic operation
- Percentile statistics function
- Phase Arithmetic function
- RadialMaximum statistics function
- RadialMean statistics function
- RadialMinimum statistics function
- RadialSum statistics function
- Real Arithmetic function
- Reciprocal arithmetic function
- RootMeanSquareError difference measure
- Select Configurable selection function
- Sign Arithmetic function
- Sin trigonometric function
- Sinc mathematical function
- Singular Value Decomposition Singular value decomposition
- Sinh trigonometric function
- Sqrt arithmetic function
- StandardDeviation statistics function
- Sub arithmetic function
- SubComplex arithmetic function

- SubFloat arithmetic function
- Sum statistics function
- SumModulus statistics function
- Tan trigonometric function
- Tanh trigonometric function
- Truncate Arithmetic function
- Variance statistics function
- WeightedAdd arithmetic function
- WeightedDiv arithmetic function
- WeightedMul arithmetic function
- WeightedSub arithmetic function
- Xor logic operation

#### 1.3.2 Statistics

- ChordLength Compute the chord lengths of the different phases
- CumulativeSum statistics function
- GetMaximumAndMinimum statistics function
- IDivergence difference measure
- LnNormError difference measure
- Maximum statistics function
- Mean statistics function
- MeanAbsoluteError difference measure
- MeanError difference measure
- MeanModulus statistics function
- MeanSquareError difference measure
- MeanSquareModulus statistics function
- Median statistics function
- Minimum statistics function
- PairCorrelation Compute the pair correlation function

- Percentile statistics function
- $\bullet \ \, \textbf{ProbabilisticPairCorrelation} \, \textbf{-} \, \, \textbf{Compute the probabilistic pair correlation function} \, \\$
- RadialMaximum statistics function
- RadialMean statistics function
- RadialMinimum statistics function
- RadialSum statistics function
- RootMeanSquareError difference measure
- StandardDeviation statistics function
- Sum statistics function
- SumModulus statistics function
- Variance statistics function

# 1.3.3 Manipulation

- Crop Remove the outer parts of an image
- dip\_PixelGetFloat Midlevel PixelIO function
- dip\_PixelGetInteger Midlevel PixelIO function
- dip\_PixelSetFloat Midlevel PixelIO function
- dip\_PixelSetInteger Midlevel PixelIO function
- ExtendRegion Image manipulation functions
- Get Get a pixel value
- GetComplex Get complex pixel value
- GetFloat Get float pixel value
- GetInteger Get integer pixel value
- GetLine Get a line from an image
- GetSlice Get a slice from an image
- Map Remaps an image
- Mirror Mirrors an image
- PutLine Put a line in an image
- PutSlice Put a slice in an image

- Resampling Interpolation function
- Rotation Interpolation function
- Rotation3d Interpolation function
- Rotation3d\_Axis Interpolation function
- $\bullet$  Set the value of a pixel
- SetComplex Set a pixel value
- SetFloat Set a pixel value
- SetInteger Set a pixel value
- Shift an image manipulation function
- Skewing Interpolation function
- Subsampling Interpolation function
- Wrap Wrap an image

# 1.3.4 Interpolation

- Resampling Interpolation function
- Rotation Interpolation function
- Rotation3d Interpolation function
- Rotation3d\_Axis Interpolation function
- Skewing Interpolation function
- Subsampling Interpolation function

# 1.3.5 Painting

- PaintBox Paint a box
- PaintDiamond Paint a diamond-shaped object
- PaintEllipsoid Paint an ellipsoid

#### 1.3.6 Linear Filters

- Convolve1d Perform a 1D convolution
- ConvolveFT Fourier transform based convolution filter
- Derivative Derivative filter
- FiniteDifference A linear gradient filter
- FiniteDifferenceEx A linear gradient filter
- GaborIIR Infinite impulse response filter
- Gaussian Filter
- Gaussett Gaussian Filter through the Fourier Domain
- Gaussiir Infinite impulse response filter
- Laplace Second order derivative filter
- SeparableConvolution FrameWork for separable convolution filters
- Sharpen Enhance an image
- SobelGradient A linear gradient filter
- Uniform Uniform filter

#### 1.3.7 Derivative Filters

- Derivative Derivative filter
- Dgg Second order derivative filter
- FiniteDifference A linear gradient filter
- FiniteDifferenceEx A linear gradient filter
- Gauss Gaussian Filter
- GaussFT Gaussian Filter through the Fourier Domain
- GradientDirection2D Derivative filter
- GradientMagnitude Derivative filter
- Laplace Second order derivative filter
- LaplaceMinDgg Second order derivative filter
- LaplacePlusDgg Second order derivative filter
- SobelGradient A linear gradient filter

## 1.3.8 Non-Linear Filters

- BiasedSigma Adaptive edge sharpening & contrast enhancing filter
- Closing Morphological closing operation
- Dilation Local maximum filter
- Erosion Local minimum filter
- GaussianSigma Adaptive Gaussian smoothing filter
- Generalised Kuwahara filter
- Kuwahara Edge perserving smoothing filter
- MedianFilter Non-linear smoothing filter
- MorphologicalSmoothing Morphological smoothing filter
- Opening Morphological opening operation
- PercentileFilter Rank-order filter
- Sigma Adaptive uniform smoothing filter
- VarianceFilter Sample Variance Filter

## 1.3.9 Binary Filters

- BinaryClosing Binary morphological closing operation
- BinaryDilation Binary morphological dilation operation
- BinaryErosion Binary morphological erosion operation
- BinaryOpening Binary morphological opening operation
- BinaryPropagation Morphological propagation of binary objects
- EdgeObjectsRemove Remove binary edge objects
- EuclideanSkeleton binary skeleton operation
- GrowRegions Dilate the regions in a labelled image
- Label Label a binary image

# 1.3.10 Mathematical Morphology

- AreaOpening Morphological filter
- BinaryClosing Binary morphological closing operation
- BinaryDilation Binary morphological dilation operation
- BinaryErosion Binary morphological erosion operation
- BinaryOpening Binary morphological opening operation
- BinaryPropagation Morphological propagation of binary objects
- Closing Morphological closing operation
- Dilation Local maximum filter
- DirectedPathOpening Morphological filter
- EdgeObjectsRemove Remove binary edge objects
- Erosion Local minimum filter
- EuclideanSkeleton binary skeleton operation
- GrowRegions Dilate the regions in a labelled image
- GrowRegionsWeighted Grow labelled regions using grey-weighted distances
- Lee Morphological edge detector
- LocalMinima Marks local minima (or regional minima)
- Maxima Detects local maxima
- Minima Detects local minima
- MorphologicalGradientMagnitude Morphological edge detector
- MorphologicalRange Morphological edge detector
- MorphologicalReconstruction Morphological filter
- MorphologicalSmoothing Morphological smoothing filter
- MorphologicalThreshold Morphological smoothing filter
- MultiScaleMorphologicalGradient Morphological edge detector
- Opening Morphological opening operation
- PathOpening Morphological filter
- SeededWatershed Morphological segmentation

- Tophat Morphological high-pass filter
- UpperEnvelope Upper envelope transform (a flooding and an algebraic closing)
- Watershed Morphological segmentation

# 1.3.11 Point Operations

- Clip Point operation
- Compare Compare grey values in two images
- ContrastStretch Point operation
- Equal Compare grey values in two images
- ErfClip Point Operation
- Greater Compare grey values in two images
- HysteresisThreshold Point Operation
- IsodataThreshold Point operation
- Lesser Compare grey values in two images
- NotEqual Compare grey values in two images
- NotGreater Compare grey values in two images
- NotLesser Compare grey values in two images
- NotZero Point Operation
- RangeThreshold Point Operation
- Select Configurable selection function
- SelectValue Point Operation
- Threshold Point Operation

# 1.3.12 Transforms

- FourierTransform Computes the Fourier transform
- HartleyTransform Computes the Hartley transform

#### 1.3.13 Distance Transforms

- EuclideanDistanceTransform Euclidean distance transform
- GreyWeightedDistanceTransform Grey weighted distance transform
- GrowRegionsWeighted Grow labelled regions using grey-weighted distances
- VectorDistanceTransform Euclidean vector distance transform

# 1.4 Application Functions

# 1.4.1 Smoothing

- Closing Morphological closing operation
- Gauss Gaussian Filter
- Gaussett Gaussian Filter through the Fourier Domain
- Kuwahara Edge perserving smoothing filter
- MedianFilter Non-linear smoothing filter
- MorphologicalSmoothing Morphological smoothing filter
- MorphologicalThreshold Morphological smoothing filter
- Opening Morphological opening operation
- PercentileFilter Rank-order filter
- Uniform Uniform filter
- Upper Envelope Upper envelope transform (a flooding and an algebraic closing)

## 1.4.2 Sharpening

• Sharpen - Enhance an image

# 1.4.3 Line and Edge Detection

- DanielsonLineDetector Line detector
- GradientMagnitude Derivative filter
- Laplace Second order derivative filter
- Lee Morphological edge detector
- MorphologicalGradientMagnitude Morphological edge detector
- MorphologicalRange Morphological edge detector
- MultiScaleMorphologicalGradient Morphological edge detector

#### 1.4.4 Extrema Detection

- LocalMinima Marks local minima (or regional minima)
- Maxima Detects local maxima
- Minima Detects local minima

# 1.4.5 Object Generation

- CityBlockDistanceToPoint Distance generation function
- EllipticDistanceToPoint Distance generation function
- EuclideanDistanceToPoint Distance generation function
- FTBox Generates the Fourier transform of a box
- FTCross Generates the Fourier transform of a cross
- FTCube Generates the Fourier transform of a cube
- FTEllipsoid Generates Fourier transform of a ellipsoid
- FTGaussian Generates the Fourier transform of a Gaussian
- FTSphere Generated Fourier transform of a sphere
- IncoherentOTF Generates an incoherent OTF
- IncoherentPSF Generates an incoherent PSF
- PaintBox Paint a box
- PaintDiamond Paint a diamond-shaped object
- PaintEllipsoid Paint an ellipsoid
- TestObjectAddNoise TestObject generation function
- TestObjectBlur TestObject generation function
- TestObjectCreate TestObject generation function
- TestObjectModulate TestObject generation function

# 1.4.6 Noise Generation

- BinaryNoise Generates an image disturbed by binary noise
- BinaryRandomVariable Binary random variable generator
- GaussianNoise Generate an image disturbed by Gaussian noise
- GaussianRandomVariable Gaussian random variable generator
- PoissonNoise Generate an image disturbed by Poisson noise
- PoissonRandomVariable Poisson random variable generator
- RandomSeed Initialise random number generator
- RandomSeedVector Initialise random number generator
- RandomVariable Random number generator
- UniformNoise Generate an image disturbed by uniform noise
- UniformRandomVariable Uniform random variable generator

## 1.4.7 Image Restoration

- AttenuationCorrection Attenuation correction algorithm
- ExponentialFitCorrection Exponential fit based attenuation correction
- PseudoInverse Image restoration filter
- SimulatedAttenuation Simulation of the attenuation process
- TikhonovMiller Image restoration filter
- TikhonovRegularizationParameter Determine the value of the regularisation parameter
- Wiener Image Restoration Filter

# 1.4.8 Shift Estimation

- CrossCorrelationFT Normalized cross-correlation using the Fourier Transform
- FindShift Estimate the shift between images

# 1.4.9 Segmentation

- HysteresisThreshold Point Operation
- IsodataThreshold Point operation
- RangeThreshold Point Operation
- SeededWatershed Morphological segmentation
- Threshold Point Operation
- Watershed Morphological segmentation

# 1.4.10 Analysis

- ChordLength Compute the chord lengths of the different phases
- DanielsonLineDetector Line detector
- ImageChainCode Extracts all chain codes from a labeled image
- Label Label a binary image
- Measure Measure object features
- PairCorrelation Compute the pair correlation function
- Probabilistic Pair Correlation Compute the probabilistic pair correlation function
- StructureTensor2D Two dimensional Structure Tensor

#### 1.4.11 Measurement

- ChainCodeArrayFree Chain code array deallocation
- ChainCodeArrayNew Chain code array allocation
- ChainCodeFree Chain code object deallocation
- ChainCodeGetChains Chain code access function
- ChainCodeGetConnectivity Chain code access function
- ChainCodeGetFeret Chain code measurement function
- ChainCodeGetLabel Chain code access function
- ChainCodeGetLength Chain code measurement function
- ChainCodeGetLongestRun Chain code measurement function
- ChainCodeGetSize Chain code access function

- ChainCodeGetStart Chain code access function
- ChainCodeNew Chain code object allocation
- FeatureAnisotropy2D Measure the anisotropy in a labeled region
- FeatureBendingEnergy Undocumented measurement function
- FeatureCenter Measure the object's center
- FeatureChainCodeBendingEnergy Undocumented measurement function

Chapter 2

Function reference

Abs

Arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Abs ( in, out )
```

## DATA TYPES

binary, integer, integer, float, complex

## **FUNCTION**

Computes the absolute value of the input image values.

# **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

# **SEE ALSO**

Ceil, Floor, Sign, Truncate, Fraction, NearestInt

# Acos

trigonometric function

# **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Acos ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the arc cosine of the input image values.

# **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

# **SEE ALSO**

Sin, Cos, Tan, Asin, Atan, Atan2, Sinh, Cosh, Tanh

# AdaptiveBanana

Performs Gaussian filtering steered by paramter images

#### **SYNOPSIS**

```
#include "dip_adaptive.h"
dip_Error DIP_TPI_FUNC(dip_AdaptiveBanana)( in, out, para_images, curv_image,
filterSize, order, truncation )
```

#### DATA TYPES

sfloat

#### **FUNCTION**

This function performs Gaussian filtering steerd by the information stored in the paramter images (local orientation) and in the curvature image. The meaning of the parameter images depends on the dimensionality of the input image. Up to now only 2 and 3D images are supported for adaptive filtering. If the input image is not of type **float** it is converted to that type.

para\_images: ImageArray containing orientation images.

2D: angle of the orientation.

3D: polar coordinate phi, theta for intrinsic 1D structures polar coordinates of two orientations for intrinsic 2D structures.

filterSize: Array containing the sigmas of the derivatives.

For intrinsic 1D structures, the first value is along the contour, the second perpendicular to it.

For intrinsic 2D structures, the first two are in the plane, whereas the other is perpendicular to them. If a value is zero no convolution is done is this direction.

# **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
dip_Image	out	Output image
dip_ImageArray	para_images	Parameter images
$\mathtt{dip}_{-}\mathtt{Image}$	curv	Curvature image
dip_FloatArray	filterSize	Size of the filter
dip_IntegerArray	order	Order of the Gaussian derivative
dip_int	truncation	Truncation of the Gaussian

Add

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Add ( in1, in2, out )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

This function computes  $\mathtt{out} = \mathtt{in1} + \mathtt{in2}$  on a pixel by pixel basis. The data types of the  $\mathtt{in1}$  and  $\mathtt{in2}$  image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in1	First input
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output

## **SEE ALSO**

AddFloat, AddComplex, Sub, SubFloat, SubComplex, Mul, MulFloat, MulComplex, Div, DivFloat, DivComplex

# AddComplex

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_AddComplex ( in, out, constant )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

This function computes out = in + constant on a pixel by pixel basis. The data types of the in1 image and constant may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
dip_complex	constant	Constant
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output

## **SEE ALSO**

 ${\tt Add,\,AddFloat,\,Sub,\,SubFloat,\,SubComplex,\,Mul,\,MulFloat,\,MulComplex,\,Div,\,DivFloat,\,DivComplex}$ 

# AddFloat

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_AddFloat ( in, out, constant )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

This function computes out = in + constant on a pixel by pixel basis. The data types of the in1 image and constant may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
dip_float	constant	Constant
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output

## **SEE ALSO**

# And

logic operation

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_And ( in1, in2, out )
```

## DATA TYPES

binary, integer

# **FUNCTION**

The function And performs the logic AND operation between the corresponding pixels in in1 and in2, and stores the result in out.

# **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in1	First binary input image
dip_Image	in2	Second binary input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image

## **SEE ALSO**

Xor, Or, Invert

# AreaOpening

Morphological filter

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_AreaOpening ( grey, mask, out, filtersize, connectivity, closing )
```

## DATA TYPES

integer, float

#### **FUNCTION**

The image grey will be filtered to remove local maxima (closing is DIP\_FALSE) or local minima (closing is DIP\_TRUE) with an area smaller than filtersize (in pixels).

Theoretically, the area opening can be written as the supremum of all the openings with each of the possible compact structuring elements of filtersize pixels. The connectivity parameter indicates which shapes are considered compact (i.e. all pixels are connected). See The connectivity parameter for more information.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	grey	Grey-value input image
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask image for ROI processing
dip_Image	out	Output image
dip_int	filtersize	Size of structuring element
dip_int	connectivity	Connectivity
dip_Boolean	closing	DIP_FALSE for area opening, DIP_TRUE for area closing

# ArrayFree

Array free function

## **SYNOPSIS**

dip\_Error dip\_ArrayFree ( array )

## **FUNCTION**

This function frees \*array, and sets array to zero.

## **ARGUMENTS**

Data type	Name	Description
dip_Array *	array	pointer to a dip_Array

## **SEE ALSO**

## ArrayNew, ArrayFree

ArrayFree, IntegerArrayFree, FloatArrayFree, ComplexArrayFree,
BoundaryArrayFree, FrameWorkProcessArrayFree, DataTypeArrayFree, ImageArrayFree,
BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

# ArrayNew

Array allocation function

## **SYNOPSIS**

dip\_Error dip\_ArrayNew ( array, size, elementSize, resources )

## **FUNCTION**

This functions allocates the size elements of a dip\_Array and sets the size of the array to size. The size of each element is determined by elementSize.

## **ARGUMENTS**

Data type	Name	Description
dip_Array *	array	Array
dip_int	size	Size
dip_int	elementSize	ElementSize
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

## ArrayNew, ArrayFree

# Asin

trigonometric function

# **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Asin ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the arc sine of the input image values.

# **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
${\tt dip\_Image}$	out	Output

# **SEE ALSO**

Sin, Cos, Tan, Acos, Atan, Atan2, Sinh, Cosh, Tanh

# Atan

trigonometric function

# **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Atan ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the arc tangent of the input image values.

# **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

# **SEE ALSO**

Sin, Cos, Tan, Asin, Acos, Atan2, Sinh, Cosh, Tanh

## Atan2

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Atan2 ( in1, in2, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function computes out = atan2(in1, in2) on a pixel by pixel basis. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in1	First input
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output

## **SEE ALSO**

Sin, Cos, Tan, Asin, Acos, Atan, Sinh, Cosh, Tanh

## AttenuationCorrection

Attenuation correction algorithm

#### **SYNOPSIS**

#include "dip\_microscopy.h"

dip\_Error dip\_AttenuationCorrection ( in, out, fAttenuation, bAttenuation, background, threshold, NA, refIndex, ratio, method )

## DATA TYPES

binary, integer, float

#### **FUNCTION**

This function implements an attenuation correction using three different recursive attenuation correction algorithms. The RAC-DET algorithm is the most accurate one, since it takes both forward and backward attenuation into account. It is however considerably slower that the RAC-LT2 and RAC-LT1 algorithms which take only forward attenuation into account. These last two algorithms assume a constant attenuation (background) for pixels with an intensity lower than the threshold.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_float	fAttenuation	Forward attenuation factor
dip_float	bAttenuation	Backward attenuation factor
dip_float	background	Background attenuation factor
dip_float	threshold	Background threshold
dip_float	NA	Numerical aperture
dip_float	refIndex	Refractive index
dip_float	ratio	Z/X sampling ratio
dipf_AttenuationCorrection	method	Correction method

The dipf\_AttenuationCorrection enumaration consists of the following flags:

Name	Description
DIP_ATTENUATION_RAC_LT2	Recursive Attenuation Correction algorithm using two Light
	Cone convolutions
DIP_ATTENUATION_RAC_LT1	Recursive Attenuation Correction algorithm using one Light
	Cone convolution
DIP_ATTENUATION_RAC_DET	Recursive Attenuation Correction algorithm using
	Directional Extinction Tracking

# BiasedSigma

Adaptive edge sharpening & contrast enhancing filter

#### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_BiasedSigma ( in, out, se, boundary, filterSize, shape, sigma,
outputCount )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

The Biased Sigma filter is an adaptive edge sharpening and contrast enhancing filter. Its operation differs from the Sigma filter by separating the averaging the pixels with an intensities higher than the pixel being filtered, from the pixels with lower intensities. The absolute difference of these two averages with the value of the pixel being filtered. The value of this pixel is being replaced by the average with the smallest difference. If outputCount is DIP\_TRUE, the output values represent the number of pixel over which the average has been calculated. When threshold is DIP\_TRUE, the pixel intensities are being thresholded at +/-2 sigma, when it is set to DIP\_FALSE, the intensities are weighted with the Gaussian difference with the intensity of the central pixel.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	in	Input image
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output image
$\mathtt{dip}_{-}\mathtt{Image}$	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterSize	Filter sizes
dip_FilterShape	shape	Filter shape
dip_float	sigma	Sigma
dip_Boolean	outputCount	Output the Count

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

65

## NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

## LITERATURE

John-Sen Lee, Digital Image Smoothing and the Sigma Filter, Computer Vision, Graphics and Image Processing, 24, 255-269, 1983

# **SEE ALSO**

Sigma, GaussianSigma

# BinaryClosing

Binary morphological closing operation

#### **SYNOPSIS**

```
#include "dip_binary.h"
dip_Error dip_BinaryClosing ( in, out, connectivity, iterations, edge )
```

#### DATA TYPES

#### binary

#### **FUNCTION**

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP\_TRUE) or as background (DIP\_FALSE). Additionally, you can set it to -1 for special handling: DIP\_FALSE for the dilation, DIP\_TRUE for the erosion; this avoids the border effect you can get in the corners of the image in some cases.

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	out	Output
dip_int	connectivity	Connectivity
dip_int	iterations	Iterations
dip_int	edge	Edge condition

#### **KNOWN BUGS**

This function is only implemented for images with a dimension up to three.

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP\_TRUE) or as background (DIP\_FALSE).

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
dip_int	connectivity	Connectivity
dip_int	iterations	Iterations
dip_Boolean	edge	Edge condition

#### **KNOWN BUGS**

This function is only implemented for images with a dimension up to three.

#### **SEE ALSO**

BinaryDilation, BinaryClosing, BinaryOpening, BinaryPropagation

# BinaryImageToPixelTable

Convert a binary image to a pixel table

## **SYNOPSIS**

```
#include "dip_pixel_table.h"
dip_Error dip_BinaryImageToPixelTable ( im, table, resources)
```

## DATA TYPES

## binary

## **FUNCTION**

This functions converts a binary image to a new allocated pixel table table.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	im	Binary image
dip_PixelTable *	table	Pixel table
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

Description of DIPlib's pixel tables

 ${\tt PixelTableToBinaryImage,\,PixelTableCreateFilter}$ 

# BinaryNoise

Generates an image disturbed by binary noise

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_BinaryNoise ( in, out, p10, p01, random )
```

## DATA TYPES

## binary

## **FUNCTION**

Generate an image disturbed by binary noise. See <code>BinaryRandomVariable</code> for more information on the random number generator.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_float	p10	Probability of a one to zero transition
dip_float	p01	Probability of a zero to one transition
dip_Random *	random	Pointer to a random value structure

## **EXAMPLE**

Get a binary noise disturbed image as follows:

```
dip_Image in, out;
dip_float p10, p01;
dip_Random random;

p10 = 0.1;
p01 = 0.2;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_BinaryNoise( in, out, p10, p01, &random ));
```

# SEE ALSO

BinaryRandomVariable, RandomVariable, RandomSeed, RandomSeedVector, UniformNoise, GaussianNoise, PoissonNoise

DIP/lib function reference

# BinaryOpening

73

Binary morphological opening operation

#### **SYNOPSIS**

```
#include "dip_binary.h"
dip_Error dip_BinaryOpening ( in, out, connectivity, iterations, edge )
```

#### DATA TYPES

#### binary

#### **FUNCTION**

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP\_TRUE) or as background (DIP\_FALSE). Additionally, you can set it to -1 for special handling: DIP\_TRUE for the erosion, DIP\_FALSE for the dilation; this avoids the border effect you can get in the corners of the image in some cases.

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_Image	out	Output
dip_int	connectivity	Connectivity
dip_int	iterations	Iterations
dip_int	edge	Edge condition

#### **KNOWN BUGS**

This function is only implemented for images with a dimension up to three.

### BinaryPropagation

75

Morphological propagation of binary objects

#### **SYNOPSIS**

```
#include "dip_binary.h"
dip_Error dip_BinaryPropagation ( seed, mask, out, connectivity, iterations, edge )
```

#### DATA TYPES

#### binary

#### **FUNCTION**

The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP\_TRUE) or as background (DIP\_FALSE).

See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of binary mathematical morphology operations, and section 10.3, "Segmentation", for applications of binary propagation.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	seed	Input seed
dip_Image	mask	Input mask
dip_Image	out	Output
dip_int	connectivity	Connectivity
dip_int	iterations (0)	Iterations
dip_Boolean	edge	Edge condition

#### **KNOWN BUGS**

This function is only implemented for images with a dimension up to three.

### BinaryRandomVariable

Binary random variable generator

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_BinaryRandomVariable ( random, input, p10, p01, output )
```

#### **FUNCTION**

The binary random variable is generated by altering the input value, if the value of a generated random variable is higher than the p10 probability, if input is DIP\_TRUE, or higher than p01 otherwise.

See RandomVariable for more information on the random number generator.

#### **ARGUMENTS**

Data type	Name	Description	
dip_Random *	random	Pointer to a random value structure	
dip_Boolean	input	Input	
dip_float	p10	Probability of a one to zero transition	
dip_float	p01	Probability of a zero to one transition	

#### **EXAMPLE**

Get a binary random variable as follows:

```
dip_Random random;
dip_float p10, p01, value;

p10 = 0.1;
p01 = 0.2;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_BinaryRandomVariable( &random, 1, p10, p01, &value ));
```

# BooleanArrayCopy

Copy an array

#### **SYNOPSIS**

dip\_Error dip\_BooleanArrayCopy ( dest, src, resources )

#### **FUNCTION**

This function copies the boolean array src to dest. The array dest is created by this function as well.

#### **ARGUMENTS**

Data type	Name	Description
dip_BooleanArray *	dest	Destination array
dip_BooleanArray	src	Source array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

### **SEE ALSO**

BooleanArrayNew, BooleanArrayFree, BooleanArrayCopy, BooleanArrayFind IntegerArrayCopy, FloatArrayCopy, ComplexArrayCopy, DataTypeArrayCopy, BooleanArrayCopy, VoidPointerArrayCopy, StringArrayCopy

# BooleanArrayFind

Find value in array

#### **SYNOPSIS**

dip\_Error dip\_BooleanArrayFind ( array, value, index, found )

#### **FUNCTION**

Finds a value in an array and "returns" its index in the array. If found is zero, BooleanArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP\_FALSE if value is not found).

#### **ARGUMENTS**

Data type	Name	Description	
dip_BooleanArray	array	Array to find value in	
dip_Boolean	value	Value to find	
dip_int *	index	Index of the found value	
dip_Boolean *	found	Value found or not	

#### **SEE ALSO**

BooleanArrayNew, BooleanArrayFree, BooleanArrayCopy, BooleanArrayFind IntegerArrayFind, FloatArrayFind, ComplexArrayFind, DataTypeArrayFind, BooleanArrayFind, VoidPointerArrayFind

# BooleanArrayFree

Array free function

#### **SYNOPSIS**

dip\_Error dip\_BooleanArrayFree ( array )

#### **FUNCTION**

This function frees \*array, and sets array to zero.

#### **ARGUMENTS**

Data type	Name	Description
dip_BooleanArray *	array	Array

### **SEE ALSO**

 $\label{thm:condition} VoidPointerArrayFree, VoidPointerArrayCopy, VoidPointerArrayFind$

# BooleanArrayNew

Array allocation function

#### **SYNOPSIS**

dip\_Error dip\_BooleanArrayNew ( array, size, value, resources )

#### **FUNCTION**

This function allocates the size elements of a dip\_BooleanArray and sets the size of the array to size. Each array element is initialized with value.

#### **ARGUMENTS**

Data type	Name	Description
dip_BooleanArray *	array	Array
dip_int	size	Size
dip_Boolean	value	Initial value
dip_Resources	resources	Resources tracking structure. See ResourcesNew

Ceil

Arithmetic function

### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Ceil ( in, out )
```

### DATA TYPES

binary, integer, **float** 

#### **FUNCTION**

Computes the ceil of the input image values, and outputs a signed integer typed image.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

# ${\tt ChainCodeArrayNew}$

Chain code array allocation

### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeArrayNew ( array, size, resources )
```

#### **FUNCTION**

This function allocates the size elements of a dip\_ChainCodeArrayNew and sets the size of the array to size.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCodeArray *	array	Receives pointer to allocated structure
dip_int	size	Number of chains to allocate space for
dip_Resources	resources	Resources tracking structure. See ResourcesNew

### **SEE ALSO**

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeArrayFree}$ 

DIPlib function reference

### ChainCodeFree

Chain code object deallocation

### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeFree ( chaincode )
```

#### **FUNCTION**

Deallocates the chaincode object created by ChainCodeNew, and sets the pointer to zero.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode *	chaincode	Pointer to chain code

### **SEE ALSO**

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeArrayNew}, {\tt ChainCodeArrayFree}$ 

### ChainCodeGetChains

Chain code access function

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetChains ( chaincode, chain )
```

#### **FUNCTION**

Returns a pointer to the first element of the chain. Each chain element contains a pointer to the next element. The last element has a NULL pointer. ChainCodeGetSize returns the number of elements in the chain. The border value in each element indicates whether the pixel is on the edge of the image or not. This usually indicates that the object is cut by the imaging window and needs to be treated differently.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Chain code
dip_Chain **	chain	Receives the pointer to the first element in the chain

The dip\_Chain structure has the following elements:

Data type	Name	Description
$\mathtt{dip}_{ ext{-}}\mathtt{int}$	code	Direction of step taken from previous to this pixel (Freeman
		code)
dip_int	border	Pixel is on the border
dip_Chain *	next	Pointer to the next element in the chain

#### **SEE ALSO**

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize, ChainCodeGetStart, ChainCodeGetLabel, ChainCodeGetConnectivity

# ChainCodeGetConnectivity

Chain code access function

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetConnectivity ( chaincode, connectivity )
```

#### **FUNCTION**

Returns the connectivity used when extracting the boundary described in chaincode. connectivity==1 indicates 4-connected neighbours, and the code uses integers 0 through 3. connectivity==2 indicates 8-connected neighbours, and the code uses values 0 through 7. See The connectivity parameter.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Chain code
dip_int *	connectivity	Receives the connectivity value in chaincode

#### SEE ALSO

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize,
ChainCodeGetChains, ChainCodeGetStart, ChainCodeGetLabel

### ChainCodeGetFeret

Chain code measurement function

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetFeret ( chaincode, stepSize, feret )
```

#### **FUNCTION**

This function measures the longest and shortest projections of the object encoded by chaincode. The chain code is rotated in stepSize degree intervals and the length of the projection on the x and y axes is computed for each orientation. The sizes of maximum and minimum projections, as well as the rotation at which they were obtained, are returned in the feret structure, which contains the following elements:

Data type	Name	Description
dip_float	maxDiameter	The widest projection of the object
dip_float	minDiameter	The narrowest projection of the object
dip_float	maxPerpendicular	The width of the projection perpendicular to
		minDiameter
dip_float	maxAngle	The angle of the projection for maxDiameter
dip_float	minAngle	The angle of the projection for minDiameter

ChainCodeGetFeret is the function used by Measure for the FeatureFeret measurement.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Input chain code
dip_float	stepSize	The step size, in degrees
dip_Feret *	feret	Output measurement

#### **CREDITS**

The original code on which the current implementation is based, was donated by Gerie van der Heijden.

### SEE ALSO

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeGetLength}, {\tt ChainCodeGetLongestRun}$ 

### ChainCodeGetLabel

Chain code access function

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetLabel ( chaincode, label )
```

#### **FUNCTION**

Returns the label ID of the object whose boundary is described by chaincode.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Chain code
dip_int *	label	Receives the label ID in chaincode

#### **SEE ALSO**

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize,
ChainCodeGetChains, ChainCodeGetStart, ChainCodeGetConnectivity

# ${\tt ChainCodeGetLength}$

Chain code measurement function

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetLength ( chaincode, length )
```

#### **FUNCTION**

Computes the length of the boundary encoded by chaincode. See FeaturePerimeter for a description of the algorithm. ChainCodeGetLength is the function used by Measure for the FeaturePerimeter measurement.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Input chain code
dip_float *	length	Output measurement

#### **SEE ALSO**

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeGetLongestRun}, {\tt ChainCodeGetFeret}, {\tt FeaturePerimeter}$ 

# ${\tt ChainCodeGetLongestRun}$

Chain code measurement function

### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetLongestRun ( chaincode, longestRun )
```

#### **FUNCTION**

Returns the number of pixels in the longest run of identical codes in chaincode. This represents the longest straight section of the boundary.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Input chain code
dip_int *	longestRun	Receives the pixel count for the longest run

### **SEE ALSO**

 ${\tt ImageChainCode}, {\tt ChainCodeNew}, {\tt ChainCodeFree}, {\tt ChainCodeGetLength}, {\tt ChainCodeGetFeret}$ 

### ChainCodeGetSize

Chain code access function

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetSize ( chaincode, number )
```

#### **FUNCTION**

Returns the number of elements in the chain code.

Note: this is not a correct measure for the object's perimeter, use ChainCodeGetLength instead.

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Chain code
dip_int *	number	Receives the number of elements in the chain.

#### **SEE ALSO**

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetChains,
ChainCodeGetStart, ChainCodeGetLabel, ChainCodeGetConnectivity

### ChainCodeGetStart

Chain code access function

### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeGetStart ( chaincode, startX, startY )
```

#### **FUNCTION**

Returns the start coordinates of the chain.

### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode	chaincode	Chain code
dip_int *	startX	Receives the start x-coordinate in chaincode
dip_int *	startY	Receives the start y-coordinate in chaincode

### **SEE ALSO**

ImageChainCode, ChainCodeNew, ChainCodeFree, ChainCodeGetSize,
ChainCodeGetChains, ChainCodeGetLabel, ChainCodeGetConnectivity

### ChainCodeNew

Chain code object allocation

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ChainCodeNew ( chaincode, resources )
```

#### **FUNCTION**

Allocates an object of type dip\_ChainCode. However, since it's fields are private and there currently exist only read access functions, it is of little use creating such an object.

A dip\_ChainCode object stores the following data:

Data type	Name	Description
dip_int	startX	Start coordinates for chain, ChainCodeGetStart
dip_int	startY	Start coordinates for chain, ChainCodeGetStart
dip_int	label	Label ID of object, ChainCodeGetLabel
$\mathtt{dip}_{-}\mathtt{int}$	connectivity	Connectivity of chain, ChainCodeGetConnectivity
dip_int	number	Number of elements in chain, ChainCodeGetSize
dip_Chain *	chain	Pointer to first element in chain, ChainCodeGetChains

#### **ARGUMENTS**

Data type	Name	Description
dip_ChainCode *	chaincode	Receives pointer to allocated structure
dip_Resources	resources	Resources tracking structure. See ResourcesNew

### **SEE ALSO**

ImageChainCode, ChainCodeFree, ChainCodeArrayNew, ChainCodeArrayFree,
ChainCodeGetSize, ChainCodeGetChains, ChainCodeGetStart, ChainCodeGetLabel,
ChainCodeGetConnectivity, ChainCodeGetLength, ChainCodeGetLongestRun,

# ChangeDataType

Change the data type of an image

#### **SYNOPSIS**

dip\_Error dip\_ChangeDataType( example, target, dataType )

#### **FUNCTION**

Inherit all properties of the input image except the data type. The data type is explicitly specified through dataType. When dataType is zero, the data type of the output image is not modified. The example image may be either "raw" or "forged".

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	example	An example image
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	target	The target image
dip_DataType	dataType	The data type

### **SEE ALSO**

DIPlib's data types

ImageCopyProperties, ImageAssimilate, ChangeToOd

### ChangeDimensions

Changes the order of the dimensions in an image

#### **SYNOPSIS**

dip\_Error dip\_ChangeDimensions( image, neworder )

#### **FUNCTION**

Re-orders the dimensions in an image, optionally removing singleton dimensions (those dimensions with size 1), without copying the data. **neworder** is a list of the dimension numbers in the new order, for example (2,1,3) will swap the first two dimensions. Setting **neworder** to 0 removes all singleton dimensions without altering the order. This is useful, for example, after calling a function such as **Maximum** to compute a maximum projection over one dimension. The output image keeps the dimensionality of the input image, and thus has a singleton dimension.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	image	The image to modify
dip_IntegerArray	neworder	The new order of the dimensions

#### SEE ALSO

The image structure

ImageGetDimensions, ImageSetDimensions, ImageGetStride

# ChangeTo0d

Make an image zero dimensional

#### **SYNOPSIS**

dip\_Error dip\_ChangeToOd( example, target, dataType )

#### **FUNCTION**

Inherit all properties of the input image except the data type and the dimensionality. The data type is explicitly specified through dataType. When dataType is zero, the data type of the output image is not modified. The dimensionality is set to zero. The example image may be either "raw" or "forged".

### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	example	An example image
$\mathtt{dip}_{-}\mathtt{Image}$	target	The target image
dip_DataType	dataType	The data type. See DIPlib's data types

### **SEE ALSO**

ImageCopyProperties, ImageAssimilate, ChangeDataType

# ChordLength

101

Compute the chord lengths of the different phases

#### **SYNOPSIS**

```
#include "dip_analysis.h"
dip_Error dip_ChordLength ( object, mask, dist, probes, length, sampling )
```

#### DATA TYPES

binary, integer

#### **FUNCTION**

This function computes the chord lengths of the different phases in object. If object is a binary image, the image is a regarded as a two phase image. In case object is of the integer type, the image is regarded as a labeled image, with each integer value encoding a phase. Optionally a mask image can be provided to select which pixels in object should be used to compute the chord lengths. The probes variable specifies how many random point pairs should be drawn to compute the lengths. Length specifies the maximum correlation length. The correlation function can be computed using a random (DIP\_CORRELATION\_ESTIMATOR\_RANDOM) or grid method (DIP\_CORRELATION\_ESTIMATOR\_GRID), as specified by sampling.

ARGU	INA	ΕN	IП	Τς
HIVGU	ועוע	-1	N I	J

Data type	Name	Description
dip_Image	object	Object image
dip_Image	mask	Mask image
dip_Distribution	dist	Ouput distribution
dip_int	probes	Number of probes
dip_int	length	Maximum chord length
dipf_CorrelationEstimator	sampling	Samplings method

#### **SEE ALSO**

PairCorrelation, ProbabilisticPairCorrelation

# CityBlockDistanceToPoint

Distance generation function

#### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_CityBlockDistanceToPoint ( output, origin, scale )
```

#### DATA TYPES

Output: sfloat

#### **FUNCTION**

Computes the cityblock distance of each pixel in the output image to a point at origin. The coordinates of origin may lie outside the image. The scale parameter may be used to specify the relative distance between pixels in each dimension.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	output	Output Image
dip_FloatArray	origin	Origin
dip_FloatArray	scale	Relative scale of the pixel distances for each dimension

### **SEE ALSO**

EllipticDistanceToPoint, EuclideanDistanceToPoint

Clip

Point operation

#### **SYNOPSIS**

```
#include "dip_point.h"
dip_Error dip_Clip ( in, out, clipLow, clipHigh, clipFlag )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Clips in at either the minimum value clipLow of the maximum value clipHigh or both. If the flag DIP\_CLIP\_THRESHOLD\_AND\_RANGE is specified, the clip bound are defined by clipLow +/- clipHigh/2.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input image
dip_Image	out	Output image
dip_float	clipLow	Lower clip bound value
dip_float	clipHigh	Higher clip bound value
dipf_Clip	clipFlag	Clip flag

The following dipf\_Clip flags are defined:

Name	Description	
DIP_CLIP_BOTH	clip both the lower and upper bound	
DIP_CLIP_LOW	clip lower bound only	
DIP_CLIP_HIGH	clip upper bound only	
DIP_CLIP_THRESHOLD_AND_RANGE	use clipLow and clipHigh as threshold and range	
	value	
DIP_CLIP_LOW_AND_HIGH_BOUNDS	same as DIP_CLIP_BOTH	

#### **SEE ALSO**

Threshold, RangeThreshold, ErfClip, ContrastStretch

### Closing

Morphological closing operation

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_Closing ( in, out, se, boundary, filterParam, shape )
```

#### DATA TYPES

integer, float, binary

#### **FUNCTION**

Grey-value closing with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape

The enumerator dip\_FilterShape contains the following constants:

DIP*lib* function reference

Name	Description	
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as	
	DIP_FLT_SHAPE_RECTANGULAR	
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element	
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element	
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element	
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element	
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element	

105

### **SEE ALSO**

Opening, Dilation, Erosion

# Colour2Gray

Convert ND image with colour information to a (n-1)D grayvalue image (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_tools.h"
dip_Error dipio_Colour2Gray ( in, out, photometric )
```

#### **FUNCTION**

This function converts a colour image, as read by ImageReadColour, to a grayvalue intensity image. in is expected to contain the colour information along the last axis. out will be a scalar image with one less dimension than the input.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dipio_PhotometricInterpretation	photometric	Photometric interpretation

The enumerator  ${\tt dipio\_PhotometricInterpretation}$  contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and
	yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta,
	yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u*
	and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a*
	and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and
	value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and
	value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as
	DIPIO_PHM_CMYK

Most file formats support only some of these.

#### **KNOWN BUGS**

Some colourspaces are not converted correctly. R'G'B' (DIPIO\_PHM\_RGB\_NONLINEAR), is treated like RGB. From a CIE Lab (DIPIO\_PHM\_CIELAB) or Luv (DIPIO\_PHM\_CIELUV) the luminosity channel is extracted, which is also a non-linear conversion away from the intensity. From HCV (DIPIO\_PHM\_HCV) and HSV (DIPIO\_PHM\_HSV) the value channel is extracted, which again is a non-linear conversion away from the intensity. CMYK (DIPIO\_PHM\_CMYK) and CMY (DIPIO\_PHM\_CMY) conversion is not implemented. Specifying these values will result in an error.

ImageRead, ImageReadColour, ImageReadROI

### Compare

Compare grey values in two images

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Compare ( in1, in2, out, selector )
```

#### DATA TYPES

binary, integer, float

### **FUNCTION**

This function can perform various pixel-by-pixel comparisons (smaller, smaller- equal, equal, not equal, greater-equal, greater) between in1 ans in2. out contains the binary result. This is implemented with a call to Select whose in3 and in4 are set to binary true and false, respectively.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to the functionality of Threshold, but with more options.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in1	First input
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
dipf_Select	selector	Select flag
Name		Description
DIP_SELECT_LESSER		<, Lesser than
DIP_SELECT_LESSER_EQUAL		<=, Lesser or equal
DIP_SELECT_NOT_EQUAL		!=, Unequal
DIP_SELECT_EQUAL		==, Equal
DIP_SELECT_GREATER_EQUAL		L >=, Greater or equal
DIP_SELECT_GREATER		>, Greater

# SEE ALSO

 ${\tt Select, Threshold, Equal, Greater, Lesser, NotEqual, NotGreater, NotLesser, SelectValue, NotZero}$ 

# ComplexArrayCopy

Copy an array

## **SYNOPSIS**

dip\_Error dip\_ComplexArrayCopy ( dest, src, resources )

## **FUNCTION**

This function copies the complex array src to dest. The array dest is created by this function as well.

## **ARGUMENTS**

Data type	Name	Description
dip_ComplexArray *	dest	Destination array
dip_ComplexArray	src	Source array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

ComplexArrayNew, ComplexArrayFree, ComplexArrayCopy, ComplexArrayFind IntegerArrayCopy, FloatArrayCopy, ComplexArrayCopy, DataTypeArrayCopy, BooleanArrayCopy, VoidPointerArrayCopy, StringArrayCopy

# ComplexArrayFind

Find value in array

## **SYNOPSIS**

dip\_Error dip\_ComplexArrayFind ( array, value, index, found )

## **FUNCTION**

Finds a value in an array and "returns" its index in the array. If found is zero, ComplexArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP\_FALSE if value is not found).

## **ARGUMENTS**

Data type	Name	Description
dip_ComplexArray	array	Array to find value in
dip_complex	value	Value to find
dip_int *	index	Index of the found value
dip_Boolean *	found	Value found or not

## **SEE ALSO**

ComplexArrayNew, ComplexArrayFree, ComplexArrayCopy, ComplexArrayFind IntegerArrayFind, FloatArrayFind, ComplexArrayFind, DataTypeArrayFind, BooleanArrayFind, VoidPointerArrayFind

# ${\tt ComplexArrayFree}$

Array free function

#### **SYNOPSIS**

dip\_Error dip\_ComplexArrayFree ( array )

## **FUNCTION**

This function frees \*array, and sets array to zero.

## **ARGUMENTS**

Data type	Name	Description	
dip_ComplexArray *	array	Array	

## **SEE ALSO**

 ${\tt ComplexArrayNew, ComplexArrayFree, ComplexArrayCopy, ComplexArrayFind}$

# ComplexArrayNew

Array allocation function

113

## **SYNOPSIS**

dip\_Error dip\_ComplexArrayNew ( array, size, value, resources )

## **FUNCTION**

This function allocates the size elements of a dip\_ComplexArray and sets the size of the array to size. Each array element is initialized with value.

## **ARGUMENTS**

Data type	Name	Description
dip_ComplexArray *	array	Array
dip_int	size	Size
dip_complex	value	Initial value
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

ComplexArrayNew, ComplexArrayFree, ComplexArrayCopy, ComplexArrayFind

## ContrastStretch

Point operation

#### **SYNOPSIS**

#include "dip\_point.h"

dip\_Error dip\_ContrastStretch ( in, out, lowerBound, upperBound, outMaximum, outMinimum, method, sigmoidSlope, sigmoidPoint, maxDecade )

## DATA TYPES

integer, float

#### **FUNCTION**

ContrastStretch stretches the pixel values of the input image. Pixel values higher or equal to UpperBound are stretched to the OutMaximum value. A similar thing holds for LowerBound and OutMinimum. Method determines how pixel values are stretched. SigmoidSlope and SigmoidPoint are used by the DIP\_CST\_SIGMOID method. MaxDecade determines the maximum number of decades the method DIP\_CST\_DECADE will stretch (values lower than MaxDecade will be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_float	lowerBound	LowerBound (%)
dip_float	upperBound	UpperBound (%)
dip_float	outMax	OutMaximum
dip_float	outMin	OutMinimum
dipf_ContrastStretch	method	Method
dip_float	sigmoidSlope	SigmoidSlope
dip_float	sigmoidPoint	SigmoidPoint
dip_float	maxDecade	MaxDecade

The following dipf\_ContrastStretch flags are defined:

Name	Description	
DIP_CST_LINEAR	linear contrast stretch	
DIP_CST_SIGNED_LINEAR	linear stretch with zero at fixed value	
DIP_CST_LOGARITHMIC	logarithmic contrast stretch	
DIP_CST_SIGNED_LOGARITHMIC	signed logarithmic contrast stretch	
DIP_CST_ERF	linear contrast stretch with erf clipping	
DIP_CST_DECADE	Decade contrast stretching	
DIP_CST_SIGMOID	Contrast stretched by sigmoid function	
DIP_CST_CLIP	Simple clipping	
DIP_CST_01	Stretching of [0,1] input values	
DIP_CST_PI	Stretching of [-Pi,Pi] input values	

In the explanaition of the different contrast stretch flags, the variables input, output, inMin, inMax, outMin and outMax are used. With input and output is meant the pixel being processed of respecitively the input and output image. inMin and inMax are the pixel values corresponding to the lowerBound and upperBound of the input image. outMin and outMax are parameters passed to the function dip\_ContrastStretch.

The DIP\_CST\_LINEAR stretches the input in the following way:

```
scale = (outMax - outMin) / (inMax - inMin)
output = scale * (MIN(inMax, MAX(inMin, input )) - inMin) + outMin
```

The DIP\_CST\_SIGNED\_LINEAR stretches the input in the following way:

```
max = MAX(inMax, ABS( inMin ));
scale = (outMax - outMin) / (2 * max)
offset = (outMax - outMin) / 2
output = scale * (MIN(inMax, MAX(inMin, input)) - offset) + outMin
```

The DIP\_CST\_LOGARITHMIC stretches the input in the following way:

```
scale = (outMax - outMin) / log( inMax - inMin + 1)
offset = inMin - 1
output = scale * log(MIN(inMax, MAX(inMin, input)) - offset) + outMin
```

The DIP\_CST\_SIGNED\_LOGARITHMIC stretches the input in the following way:

```
max = MAX(inMax, ABS(inMin))
scale = (outMax - outMin) / (2 * log(max + 1))
offset = (outMax + outMin) / 2
output = scale * log(MIN(inMax, MAX(inMin, input)) - offset) + outMin
```

The DIP\_CST\_ERF stretches the input in the following way:

```
scale = (outMax - outMin) / (inMax - inMin)
```

```
threshold = (inMax + inMin)/ 2
range = inMax - inMin
in = MIN(inMax, MAX(inMin, input))
out = (range / 2) * erf( SQRT_PI * (in - threshold) / range )
output = scale * (out + threshold ) + outMin
```

The DIP\_CST\_DECADE stretches the input in the following way:

```
inScale = inMax - inMin
outScale = outMax - outMin
in = MIN(inMax, DIP_MAX(inMin, input))
decade = log10(inScale / (in - inMin + EPSILON))
if(decade < maxDecade)
  decade -= floor(decade)
  output = outScale * (1 - decade) + outMin
else
  output = 0</pre>
```

The DIP\_CST\_SIGMOID stretches the input in the following way:

The DIP\_CST\_CLIP stretches the input in the following way:

```
output = MIN(outMax, MAX(outMin, input))
```

The DIP\_CST\_01 stretches the input in the following way:

```
scale = (outMax - outMin)
output = scale * input + outMin
```

The DIP\_CST\_01 stretches the input in the following way:

```
scale = (outMax - outMin) / 2 * Pi
output = scale * (input + Pi) + outMin
```

## **SEE ALSO**

# ConvertArray

converts the data type of an array

## **SYNOPSIS**

```
#include "dip_convert_array.h"
dip_Error DIP_TWO_FUNC(dip_ConvertArray)( in, inStride, inPlane, out,
outStride, outPlane, number )
```

## **FUNCTION**

Converts the in array to the out array.

## **ARGUMENTS**

Data type	Name	Description
void *	in	input array
dip_int	inStride	Stride of the input array
dip_int	inPlane	plane number in case in is a binary array
void *	out	output array
dip_int	outStride	Stride of the output array
dip_int	outPlane	plane number in case out is a binary array
dip_int	number	size of the arrays

# ConvertDataType

Converts the data type of an image

## **SYNOPSIS**

```
#include "dip_tpscalar.h"
dip_Error dip_ConvertDataType ( in, out, dataType )
```

## **FUNCTION**

Convert the data type of the input data to dataType and stores the result in out.

Conversion from a *complex* type to another (non-complex) type, is done by taking the real part.

Conversion to a *binary* type from another (non-binary) type, is done as follows; any non-zero number becomes 1, zero becomes zero.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
dip_Image	out	Output
dip_DataType	dataType	Data type. See DIPlib's data types

## Convolve1d

119

Perform a 1D convolution

#### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error DIP_TPI_FUNC(dip_Convolve1d)( in, out, filter, size, filterSize, origin, flags, boundary )
```

#### DATA TYPES

#### integer, float

#### **FUNCTION**

This function performs a one-dimensional convolution of the input data with the given filter kernel. In general your filter will be centered around the origin. The origin is uniquely defined if the filter size is odd, but if the filter size is even you'll have to specify whether the origin of the filter lies to the left or the right. Words cannot possibly suffice here, so here is a small pictorial representation:

```
filter size is odd:

kernel data:

x x x x x x x x 0
0

filter size is even and

DIP_CNV_LEFT is specified: kernel data:

x x x x x x x x 0
0

DIP_CNV_RIGHT is specified: kernel data:

x x x x x x x x x 0
0
```

When the filter size is even, one of the flags <code>DIP\_CNV\_LEFT</code> or <code>DIP\_CNV\_RIGHT</code> must be specified. When the filter size is odd both flags are ignored. It is also possible to specify the origin of the filter directly by using the <code>DIP\_CNV\_USE\_ORIGIN</code> flag in combination with the <code>origin</code> parameter. Again a small pictorial representation:

0

when DIP\_CNV\_USE\_ORIGIN is NOT specified origin is computed as follows:

```
filter size odd origin = (filterSize - 1) / 2
filter size even _and_
   DIP_CNV_LEFT origin = (filterSize / 2) - 1
   DIP_CNV_RIGHT origin = filterSize / 2
```

The input data is copied to a temporary buffer, after which the input data is extended according to the boundary condition specified. You can use the flags <code>DIP\_CNV\_HAS\_BORDER</code> to indicate that the input data already has a border. In this case you must make sure that there are enough pixels on either size of the array:

```
on the left : ((filterSize - 1) - origin) pixels on the right: (origin) pixels
```

If DIP\_CNV\_HAS\_BORDER is specified and in != out no auxiliary storage is used. You must also specify the symmetry of the filter as follows:

```
odd filter size : a b c b a DIP_CNV_EVEN
a b c -b -a DIP_CNV_ODD
a b c d e DIP_CNV_GENERAL

even filter size : a b c c b a DIP_CNV_EVEN
a b c -c -b -a DIP_CNV_ODD
a b c d e f DIP_CNV_GENERAL
```

#### **ARGUMENTS**

Data type	Name	Description	
void *	in	Pointer to the input data	
void *	out	Pointer to the output data	
void *	filter	Pointer to the filter data	
dip_int	size	Size of the input data	
dip_int	filterSize	Size of the filter	
dip_int	origin	Origin of the filter. Only valid in conjunction with	
		DIP_CNV_USE_ORIGIN	
${\tt dipf\_Convolve}$	flags	A combination of the flags described above	
dip_Boundary	boundary	One of the standard boundary conditions. See Boundary	
		conditions

## ConvolveFT

Fourier transform based convolution filter

## **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_ConvolveFT ( in, psf, out, inrep, psfrep, outrep )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

This function convolves the input image with the point spread function psf, by multiplying their Fourier transforms. The inrep, psfrep and outrep specify whether the images are spatial images (DIP\_IMAGE\_REPRESENTATION\_SPATIAL) or their Fourier transform. (DIP\_IMAGE\_REPRESENTATION\_SPECTRAL).

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	psf	Psf image
$ extstyle{dip\_Image}$	out	Output image
${ t dipf\_ImageRepresentation}$	inrep	Input spatial or spectral
${\tt dipf\_ImageRepresentation}$	psfrep	PSF spatial or spectral
dipf_ImageRepresentation	outrep	Output spatial or spectral

## **SEE ALSO**

# CoordinateArrayFree

Array free function

## **SYNOPSIS**

dip\_Error dip\_CoordinateArrayFree ( array )

## **FUNCTION**

This function frees \*array, and sets array to zero.

## **ARGUMENTS**

Data type	Name	Description
dip_CoordinateArray *	array	Array

## **SEE ALSO**

CoordinateArrayNew, CoordinateArrayFree

ArrayFree, IntegerArrayFree, FloatArrayFree, ComplexArrayFree,
BoundaryArrayFree, FrameWorkProcessArrayFree, DataTypeArrayFree, ImageArrayFree,
BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

# CoordinateArrayNew

Array allocation function

#### **SYNOPSIS**

dip\_Error dip\_CoordinateArrayNew ( array, ndims, size, resources )

## **FUNCTION**

This function allocates the size elements of a dip\_CoordinateArray and sets the size of the array to size. Each element has ndims values, to store coordinates of an ndims-dimensional image. Each array element is initialized to 0.

## **ARGUMENTS**

Data type	Name	Description
dip_CoordinateArray *	array	Array
dip_int	ndims	Dimensionality
dip_int	size	Size
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

 ${\tt CoordinateArrayNew}, {\tt CoordinateArrayFree}$ 

ArrayNew, IntegerArrayNew, FloatArrayNew, ComplexArrayNew, BoundaryArrayNew, FrameWorkProcessArrayNew, DataTypeArrayNew, ImageArrayNew, BooleanArrayNew, VoidPointerArrayNew, StringArrayNew, CoordinateArrayNew

# CoordinateToIndex

Convert coordinate to pixel index

## **SYNOPSIS**

```
#include "dip_coordsindx.h"
dip_Error dip_CoordinateToIndex ( coordinates, index, stride )
```

## **FUNCTION**

This function converts a pixel coordinate to an pixel index which is specific for the image from which stride was obtained. coordinages and stride must have the same number of elements.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{ extsf{-}}\mathtt{IntegerArray}$	coordinates	Coordinate array
dip_int *	index	Pointer to pixel index
dip_IntegerArray	stride	stride array

## SEE ALSO

 ${\tt IndexToCoordinate}$ 

Cos

trigonometric function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Cos ( in, out )
```

## DATA TYPES

binary, integer, **float**, **complex** 

## **FUNCTION**

Computes the cosine of the input image values.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

Sin, Cos, Tan, Asin, Acos, Atan, Atan2, Sinh, Cosh, Tanh

# Cosh

trigonometric function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Cosh ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the hyperbolic cosine of the input image values.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

Sin, Cos, Tan, Asin, Acos, Atan, Atan2, Sinh, Tanh

# Crop

Remove the outer parts of an image

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_Crop ( in, out, origin, size )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Crop a part of the image. The requested part is selected by specifying its upper left corner (origin ), and its size (size ). If in has a different type than out, it will be converted to the type of out.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input Image
dip_Image	out	Output Image
dip_IntegerArray	origin	Coordinate in in of the upper left corner of the section
dip_IntegerArray	size	Size of the new image

## **SEE ALSO**

GetSlice, GetLine

## CrossCorrelationFT

129

Normalized cross-correlation using the Fourier Transform

#### **SYNOPSIS**

```
#include "dip_findshift.h"
dip_Error dip_CrossCorrelationFT ( in1, in2, out, in1rep, in2rep, outrep )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

This function calculates the cross-correlation between two images of equal size. The returned image is the cross-correlation normalized in such a way that only the phase information is of importance. This results as a very sharp peak in the spatial domain. This function performs out = (Conj(in1)\*in2)/((Abs(in1))^2) in the Fourier domain. It is used by FindShift. The inrep, psfrep and outrep specify whether the images are spatial images (DIP\_IMAGE\_REPRESENTATION\_SPATIAL) or their Fourier transform. (DIP\_IMAGE\_REPRESENTATION\_SPECTRAL).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in1	Input image
dip_Image	in2	Input image
dip_Image	out	Output image
dipf_ImageRepresentation	in1rep	Input 1 spatial or spectral
dipf_ImageRepresentation	in2rep	Input 2 spatial or spectral
dipf_ImageRepresentation	outrep	Output spatial or spectral

## **SEE ALSO**

FindShift

## CumulativeSum

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_CumulativeSum ( in, mask, out, ps )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Calculates the cumulative sum of the pixel values over all those dimensions which are specified by ps, i.e.:

 $\operatorname{out}(x,y)=\sup_{i=0:x,j=0:y}\inf(i,j)$  when ps specifies both x and y  $\operatorname{out}(x,y)=\sup_{j=0:y}\inf(x,j)$  when ps specifies only y

## **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in	Input
$dip_{-}Image$	mask (0)	Mask
dip_Image	out	Output
dip_BooleanArray	ps (0)	Dimensions to project

## **SEE ALSO**

From images to scalars

## DanielsonLineDetector

Line detector

#### **SYNOPSIS**

```
#include "dip_orientation.h"
dip_Error dip_DanielsonLineDetector ( in, line, energy, angle, boundary,
sigma, truncation, flavour )
```

## DATA TYPES

binary, integer, float

#### **FUNCTION**

The Danielson line dectector uses second derivatives to detect lines in 2D images and to estimate their orientation. See the literature reference for an in-depth information on this detector.

## **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in	Input image
dip_Image	line	Line image
$\mathtt{dip}_{-}\mathtt{Image}$	energy	Energy image
dip_Image	angle	Angle image
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	sigma	Sigma of second derivatives
dip_float	truncation	Gauss Truncation
dip_DerivativeFlavour	flavour	Derivative filter flavour

## **LITERATURE**

# DataTypeAllowed

Check whether a data type is allowed

## **SYNOPSIS**

dip\_Error dip\_DataTypeAllowed( dataType, allow, allowedTypes, allowed )

## **FUNCTION**

This function checks whether the dataType is (or is not) in the set of data types specified by allowedTypes. If allow is DIP\_TRUE, the data type should be in this set. If allow is DIP\_FALSE, the data type should not be in this set. If the allowed parameter is zero, the routine returns dip\_errorDataTypeNotSupported if the required condition is not satisfied. If nonzero, it should point to a boolean variable. This boolean variable will be set to DIP\_TRUE if the condition is satisfied, or DIP\_FALSE if not.

## **ARGUMENTS**

Data type	Name	Description
dip_DataType	dataType	The data type to check
dip_Boolean	allow	DIP_TRUE: check if the data type is
		included. DIP_FALSE: check if the data type
		is not included
dip_DataTypeProperties	allowedTypes	The set of data types to check against, see
		DataTypeGetInfo
dip_Boolean *	allowed	Pointer to a boolean to store the answer, or
		0 to indicate that
		$ exttt{dip\_errorDataTypeNotSupported}  ext{ should}$
		be returned if the condition is not satisfied

## **SEE ALSO**

# DataTypeGetInfo

Get information about a data type

## **SYNOPSIS**

dip\_Error dip\_DataTypeGetInfo( dataType, info, whatInfo )

## **ARGUMENTS**

Data type	Name	Description
dip_DataType	dataType	The data type to get information about
void *	info	Pointer to a variable to put the information in
dipf_DataTypeGetInfo	whatInfo	What information should be returned

#### **FUNCTION**

Get information about a data type. Depending on the whatInfo flag this routine will return information about the data type through the info parameter. A pointer must be passed to this routine which must point to a variable of the proper type to contain the information which will be returned. This pointer is passed as a void pointer through the info parameter. Below is a table of the flags that determine what information is returned, the type of the variable that is used to store the information in and a description of the information that is returned.

dipf_DataTypeGetInfo	type	description
DIP_DT_INFO_PROPS	dip_DataTypeProperties	a set of flags as shown in
		the table below
DIP_DT_INFO_SIZEOF	dip_int	sizeof( data type )
DIP_DT_INFO_C2R	dip_DataType	for complex types returns
		the corresponding floating
		point type (i.e.
		dip_scomplex ->
		dip_sfloat) for other data
		types returns the data type
		itself

The following table shows which dip\_DataTypeProperties flags are set for which data types:

Data type identifier group	data types
DIP_DT_IS_UINT	unsigned integer
DIP_DT_IS_UNSIGNED	unsigned integer
DIP_DT_IS_SINT	signed integer
DIP_DT_IS_INT	signed and unsigned integer
DIP_DT_IS_INTEGER	signed and unsigned intege
DIP_DT_IS_FLOAT	floating-point

## Derivative

Derivative filter

#### **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_Derivative ( in, out, boundary, ps, sigmas, order, truncation,
flavour )
```

#### DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float** 

#### **FUNCTION**

This function provides a common interface to different families of regularised derivative operators. Which family is used, is specified by the flavour parameter. The order of the derivative operator along each of the cartesian axes may be specified independently.

Be sure to read the documentation on the underlying implementation to learn about the properties and limitations of the various families.

For the Gaussian family of filters, sigmas must be given, but order can be 0 (only smooth, don't take the derivative).

For the finite difference filter, sigmas can be 0, in which case the non-derivative dimensions will not be processed. Any element of sigmas that is non-zero where the corresponding order is zero, indicates a dimension that will be smoothed. Note it's possible to reporduce the SobelGradient filter this way.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_BoundaryArray	bc	Boundary conditions
dip_BooleanArray	ps (0)	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_int	order (0)	Derivative order
dip_float	truncation	Truncation
dip_DerivativeFlavour	flavour	Derivative filter flavour

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

## **SEE ALSO**

See section 9.5, "Derivative-based operations", in Fundamentals of Image Processing. Gauss, GaussFT, GaussIIR, FiniteDifferenceEx, GradientMagnitude, GradientDirection2D, Laplace, SobelGradient

Dgg

Second order derivative filter

## **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_Dgg ( in, out, boundary, ps, sigmas, tc, flavour )
```

## DATA TYPES

Depends on the underlying implementation, but expect:

binary, integer, float

## **FUNCTION**

Computes the second derivative in gradient direction of an image using the Derivative function.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}Image$	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	ps	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_float	tc	Truncation of Gaussian
dip_DerivativeFlavour	flavour	Derivative flavour

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

## Dilation

Local maximum filter

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_Dilation ( in, out, se, boundary, filterParam, shape )
```

#### DATA TYPES

integer, float, binary

#### **FUNCTION**

Grey-value dilation with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# DirectedPathOpening

Morphological filter

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error DirectedPathOpening ( grey, mask, out, filterParam, closing, constrained )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

Theoretically, the path opening can be written as the supremum of all the openings with each of the possible linear structuring elements of composed of a set number of pixels in the general orientation of filterParam. The filterParam parameter is interpreted as follows: length is set to max(filterParam). direction is set to round(filterParam/length). direction now contains only values 0, -1 or 1. A 90 degree cone is defined around the given direction, and this cone gives the neighbourhood connectivity. The structuring element is formed by length pixels connected according to this neighbourhood connectivity. For example, in 2D, if filterParam is [10,0], the structuring element will be formed by 10 pixels connected either diagonally or horizontally. It will extend across exactly 10 horizontal pixels, but can vary in shape to adapt to local image content.

If closing is DIP\_TRUE, the path closing will be computed instead of the opening.

If constrained is DIP\_TRUE, the algorithm is modified as follows: Only one consecutive step is allowed in a direction other than the exact direction specified. For example, following the [10,0] example above, a diagonal step must be followed by at least one horizontal step. This avoids zig-zag lines, especially if the main direction is diagonal. It also reduces the maximal angle that a straight line can deviate from the chosen direction. The unconstrained algorithm will keep lines rotated by up to 45 degrees; the constrained algorithm limits this to 22.5 degrees.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	grey	Grey-value input image
dip_Image	mask	Mask image for ROI processing
dip_Image	out	Output image
dip_FloatArray	filterParam	Size of structuring element
dip_Boolean	closing	DIP_FALSE for path opening, DIP_TRUE for path closing
dip_Boolean	constrained	DIP_TRUE for constrained paths, DIP_FALSE for the
		original path opening algorithm

Div

arithmetic function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Div ( in1, in2, out )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

This function computes out = in1 / in2 on a pixel by pixel basis. If a pixel in in2 has the value of zero, the corresponding pixel in out will be set to zero. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in1	First input
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input
dip_Image	out	Output

# EdgeObjectsRemove

Remove binary edge objects

157

#### **SYNOPSIS**

```
#include "dip_binary.h"
dip_Error dip_EdgeObjectsRemove ( in, out, connectivity )
```

#### DATA TYPES

#### binary

#### **FUNCTION**

The function EdgeObjectsRemove removes those binary objects from in which are connected to the edges of the image. The connectivity of the objects is determined by connectivity. This function is a front-end to BinaryPropagation. It calls BinaryPropagation with no seed image and the edge pixels turned on. The result of the propagation is xor-ed with the input image. The connectivity parameter defines the metric, that is, the shape of the structuring element. 1 indicates city-block metric, or a diamond-shaped structuring element. 2 indicates chessboard metric, or a square structuring element. -1 and -2 indicate alternating connectivity and produce an octagonal structuring element. See The connectivity parameter for more information. The edge parameter specifies whether the border of the image should be treated as object (DIP\_TRUE) or as background (DIP\_FALSE).

See section 10.3, "Segmentation", in Fundamentals of Image Processing for a description of the edge object removal operation.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Binary input image
dip_Image	out	Output
dip_int	connectivity	Pixel connectivity

#### **KNOWN BUGS**

This function is only implemented for images with a dimension up to three.

# EllipticDistanceToPoint

Distance generation function

159

#### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_EllipticDistanceToPoint ( output, origin, scale )
```

#### DATA TYPES

Output: sfloat

#### **FUNCTION**

Computes the elliptic distance of each pixel in the output image to a point at origin. The coordinates of origin may lie outside the image. The scale parameter may be used to specify the relative distance between pixels in each dimension.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	output	Output Image
dip_FloatArray	origin	Coordinates of the Origin
dip_FloatArray	scale	Relative scale of the pixel distances for each dimension

### **SEE ALSO**

# Equal

Compare grey values in two images

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Equal ( in1, in2, out )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function sets each pixel in out to "true" when corresponding pixels in in1 and in2 are equal. This is the same as Compare with the DIP\_SELECT\_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to SelectValue.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	in1	First input
$dip_{-}Image$	in2	Second input
$dip_{-}Image$	out	Output

# ErfClip

Point Operation

#### **SYNOPSIS**

```
#include "dip_point.h"
dip_Error dip_ErfClip ( in, out, threshold, range, clipFlag )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Clips in using the erf function at either or both the values threshold +/- range/2. If the flag DIP\_CLIP\_LOW\_AND\_HIGH\_BOUNDS is specified, threshold and range are used as lower and upper bounds respectively.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_float	threshold	Threshold value
dip_float	range	Range value
dipf_Clip	clipFlag	clipFlag

The following dipf\_Clip flags are defined:

Name	Description
DIP_CLIP_BOTH	clip both the lower and upper bound
DIP_CLIP_LOW	clip lower bound only
DIP_CLIP_HIGH	clip upper bound only
DIP_CLIP_THRESHOLD_AND_RANGE	same as DIP_CLIP_BOTH
DIP_CLIP_LOW_AND_HIGH_BOUNDS	use threshold and range as lower and upper bounds

error.h

Contains error messages

#### **SYNOPSIS**

#include "dip\_error.h"

#### **FUNCTION**

Contains a lot of definitions to do with DIPlib's error mechanism. In particular, this include file contains definitions for a number of error messages. These are all of the type extern const char \*. A list of the error sorted by category follows below:

#### Memory allocation

Name	Description
dip_errorCouldNotAllocateMemory	No memory could be allocated

#### Image creation errors

Name	Description
$ ext{dip\_errorImageIsLocked}$	Image is locked
dip_errorImageNotRaw	Image is not in the RAW state
dip_errorImageNotValid	Image is not in the VALID state
$ ext{dip\_errorImagesNotUnique}$	Image is used as an output image more than once
$ ext{dip\_errorImageLockInvalidKey}$	Cannot unlock. Wrong key

#### Image type errors

Name	Description
dip_errorIllegalImageType	Illegal image type
dip_errorImageTypeDoesNotExist	Image type does not exist
dip_errorImageTypeAlreadyExists	Adding image type failed. Type already exists
dip_errorImageTypeNotSupported	Image type not supported
dip_errorImageTypeHandlerMissing	No type handler for image type

### Image data type errors

Name	Description
${ t dip\_errorDataTypeNotSupported}$	Data type not supported
dip_errorIllegalDataType	Illegal data type

### Image dimension(ality) errors

Name	Description
$ ext{dip\_errorIllegalDimensionality}$	Illegal dimensionality
dip_errorDimensionalityNotSupported	Dimensionality not supported
dip_errorIllegalDimension	Illegal dimension

# ErrorFree

Free a DIPlib call tree

# **SYNOPSIS**

void dip\_ErrorFree( error )

# **FUNCTION**

Free a DIPlib call tree.

# **ARGUMENTS**

Data type	Name	Description
dip_Error	error	DIPlib call tree

### **RETURNS**

Nothing

# EuclideanDistanceToPoint

Distance generation function

### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_EuclideanDistanceToPoint ( output, origin )
```

#### DATA TYPES

Output: sfloat

#### **FUNCTION**

Computes the Euclidean distance of each pixel in the output image to a point at origin. The coordinates of origin may lie outside the image.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	output	Output Image
dip_FloatArray	origin	Coordinates of the Origin

### **SEE ALSO**

EllipticDistanceToPoint, CityBlockDistanceToPoint

### EuclideanDistanceTransform

Euclidean distance transform

#### **SYNOPSIS**

```
#include "dip_distance.h"
dip_Error dip_EuclideanDistanceTransform ( in, out, distance, border, method
)
```

#### DATA TYPES

#### binary

#### **FUNCTION**

This function computes the Euclidean distance transform of an input binary image using the vector-based method as opposed to the chamfer method. This method computes distances from the objects (binary 1's) to the nearest background (binary 0's) of in and stored the result in out. The out image is a sfloat type image.

The distance parameter can be used to specify anisotropic sampling densities. If it is set to zero, the sampling density is assumed to be 1.0 along all axes.

The border parameter specifies whether the edge of the image should be treated as objects (border = DIP\_TRUE) or as background (border = DIP\_FALSE).

Individual vector components of the Euclidean distance transform can be obtained with the VectorDistanceTransform.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_FloatArray	distance	Sampling distances
dip_Boolean	border	Image border type
dipf_DistanceTransform	method	Transform method

dipf\_DistanceTransform defines the following distance transform types:

Name	Description
DIP_EDT_FAST	fastest, but most errors
DIP_EDT_TIES	slower, but fewer errors
DIP_EDT_TRUE	slow, uses lots of memory, but is "error free"
DIP_EDT_BRUTE_FORCE	gives a result from which errors are calculated for the other
	methods. This method is extremly slow and should only be used
	for testing purposes.

#### **LITERATURE**

Danielsson, P.E. (1980). "Euclidean distance mapping." Computer Graphics and Image Processing 14: 227-248.

Mullikin, J.C. (1992). "The vector distance transform in two and three dimensions." CVGIP: Graphical Models and Image Processing 54(6): 526-535.

Ragnemalm, I. (1990). Generation of Euclidean Distance Maps, Thesis No. 206. Licentiate thesis. Linkoing University, Sweden.

Ye, Q.Z. (1988). "The signed Euclidean distance transform and its applications." in Proceedings, 9th International Conference on Pattern Recognition, Rome, 495-499.

#### **KNOWN BUGS**

The EDT\_TRUE transform type is prone to produce an internal buffer overflow when applied to larger (almost) spherical objects. It this cases use EDT\_TIES or EDT\_BRUTE\_FORCE instead.

The option border = DIP\_FALSE is not supported for EDT\_BRUTE\_FORCE.

This function supports 2 and 3-dimensional images.

### EuclideanSkeleton

binary skeleton operation

#### **SYNOPSIS**

#include "dip\_binary.h"
dip\_Error dip\_EuclideanSkeleton ( in, out, endpixelCondition, edgeCondition )

#### DATA TYPES

#### binary

#### **FUNCTION**

This function calculates an accurate (euclidean)skeleton. It tests Hilditch conditions to preserve topology. The algorithms uses the following distance metrics:

#### 2D

5	4-connected neighbor
7	8-connected neighbor
11	neighbors reachable with a knight's move
9D	

3D	
4	

4	6-connected neighbors
6	18-connected neighbors
7	26-connected neighbors
9	neighbors reachable with knight's move
10	(2,1,1) neighbors
12	(2,2,1) neighbors

The edge parameter specifies whether the border of the image should be treated as object (DIP\_TRUE) or as background (DIP\_FALSE). See section 9.6, "Morphology-based operations", in Fundamentals of Image Processing for a description of the skeleton operation.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Binary input image
dip_Image	out	Output image
dip_EndpixelCondition	endpixelCondition	Endpixel condition
dip_Boolean	edgeCondition	Edge condition

The dip\_EndpixelCondition enumeration consists of the following flags:

Name	Description
DIP_ENDPIXEL_CONDITION_LOOSE_ENDS_AWAY	Loose ends are eaten away
DIP_ENDPIXEL_CONDITION_NATURAL	"natural" endpixel condition of
	this algorithm
DIP_ENDPIXEL_CONDITION_KEEP_WITH_ONE_NEIGHBOR	Keep endpoint if it has a
	neighbor
DIP_ENDPIXEL_CONDITION_KEEP_WITH_TWO_NEIGHBORS	Keep endpoint if it has two
	neighbors
DIP_ENDPIXEL_CONDITION_KEEP_WITH_THREE_NEIGHBORS	Keep endpoint if it has three
	neighbors

173

### **KNOWN BUGS**

EuclideanSkeleton is only implemented for 2 and 3 D images.

EuclideanSkeleton does not process pixels in a 2-pixel border around the edge. If this is an issue, consider adding 2 pixels on each side of your image.

# ExponentialFitCorrection

Exponential fit based attenuation correction

#### **SYNOPSIS**

```
#include "dip_microscopy.h"
dip_Error dip_ExponentialFitCorrection ( in, out, method, percentile,
fromWhere, hysteresis, varWeighted )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This routine implements a simple absorption, reflection and bleaching correction based upon the assumption that the sum of these effects result in a exponential extinction of the signal as a function of depth. Only pixels that are non-zero are taken into account. Depending upon the chosen method, the mean or a percentile of all the non-zero pixels are calculated as a function of the slice number (depth). Then an exponential function is fitted through these slice-representing values. The starting point of the fit is determined by from Where. The first maximum is found with point [z+1] > b hysteresis \* point [z]. If the mean variant is chosen one can chose to apply a variance weighting to the fit.

#### **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in	Input image
dip_Image	out	Output image
dipf_ExpFitData	method	Data statistic to fit on
dip_float	percentile	Percentile
dipf_ExpFitStart	fromWhere	From where to start the fit
dip_float	hysteresis	First maximum hysteresis
dip_Boolean	varWeighted	Fit with variance weights

The dipf\_ExpFitData enumaration consists of the following flags:

Name	Description
DIP_ATTENUATION_EXP_FIT_DATA_MEAN	Fit on the mean values
DIP_ATTENUATION_EXP_FIT_DATA_PERCENTILE	Fit on the specified percentile of the data

The dipf\_ExpFitStart enumaration consists of the following flags:

Name	Description
DIP_ATTENUATION_EXP_FIT_START_FIRST_PIXEL	Start fit on first pixel
DIP_ATTENUATION_EXP_FIT_START_GLOBAL_MAXIMUM	Start fit on global maximum
DIP_ATTENUATION_EXP_FIT_START_FIRST_MAXIMUM	Start fit on first maximum

# ExtendRegion

Image manipulation functions

# **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_ExtendRegion ( image, origin, regDims, bc, ordering, imValues )
```

# **FUNCTION**

This functions extends a region in an image with a specified boundary condition.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Image
dip_IntegerArray	origin	Origin
dip_IntegerArray	regDims	RegDims
dip_BoundaryArray	bc	Boundary conditions
dip_IntegerArray	ordering	Ordering
dip_Image *	imValues	Complex values

## FeatureAnisotropy2D

Measure the anisotropy in a labeled region

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_FeatureAnisotropy2DID ( dip_int * )
```

#### **FUNCTION**

dip\_FeatureAnisotropy2DID returns the ID value of this measurement function, that is registered by Initialise.

The grey value input image should contain an orienation field. For each labeled region, a tensor is constructed at each of the region's pixels. This tensor is as follow:

```
cos^2(phi) cos(phi)sin(phi)
[
cos(phi)sin(phi) sin^2(phi)
```

The next step is to compute a new tensor, each element computed by averaging the corresponding elements of all the individual tensors. This average tensor represents the orientation information of the region as a whole. Eigenvalue analysis of this tensor yields two eigenvalues, the largest 10, the smallest 11. The anisotropy measure is:

```
(10 - 11) / (10 + 11)
```

which is zero for a fully isotropic regions (i.e. one where there is no prefered orientation), and one for a fully anisotropic region (i.e. when there is a single orientation).

#### Measure

# ${\tt Feature Bending Energy}$

Undocumented measurement function

#### **FUNCTION**

This measurement function is undocumented and not meant for public use. Measure

## FeatureCenter

183

Measure the object's center

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureCenterID ( void )
```

#### **FUNCTION**

dip\_FeatureCenterID returns the ID value of this measurement function, that is registered by Initialise.

This functions measures the centre of an object by calculating the first moments of the object using the object labels as binary mask. The intensity information is not taken into account.

## SEE ALSO

#### Measure

## FeatureChainCodeBendingEnergy

Undocumented measurement function

#### **FUNCTION**

This measurement function is undocumented and not meant for public use.

NOTE: this function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

#### Measure

## FeatureChainCodeFunction

Measurement feature #measure function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureChainCodeFunction) ( measurement, featureID, objectID, chaincode, iterations )
```

## **FUNCTION**

The chaincode measure function is meant for 2-D measurement functions that only require information on the shape of the object's contour, such as FeaturePerimeter. The chaincode function is called for each object seperately, with the contour of that object stored in chaincode.

## **ARGUMENTS**

Data type	Name	Description	
dip_Measurement	measurement	Measurement data structure	
dip_int	featureID	Measurement function ID	
dip_int	objectID	ID of the object to be measured	
dip_ChainCode	chaincode	Chaincode data structure encoding the object's	
		contour	
dip_int	iterations	Number of iterations the measure function needs to	
		scan the data	

## SEE ALSO

 ${\tt MeasurementFeatureRegister, FeatureLineFunction, FeatureImageFunction, FeatureCompositeFunction, FeatureCreateFunction}$ 

# FeatureComposeFunction

Measurement feature #compose function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureComposeFunction) ( measurement, featureID, label,
intensity, compositeFeatureID, resources )
```

## **FUNCTION**

The compose function is called to obtain a list of measurement features. These features are measured before the measure function of a composite feature is called (FeatureCompositeFunction). This parameter is ignored for other measurement types. The compose function is called after the create function (FeatureCreateFunction).

## **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement feature function ID
$\mathtt{dip}_{-}\mathtt{Image}$	label	Image with pixel intensities represending
		object IDs
dip_Image	intensity	Image containing corresponding intensity
		values
dip_IntegerArray *	compositeFeatureID	Pointer to an integer array containing the
		the IDs of the measurement features this
		function requires
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

## SEE ALSO

MeasurementFeatureRegister, FeatureCompositeFunction

## FeatureCompositeFunction

Measurement feature #measure function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureCompositeFunction) ( measurement, featureID, objectID,
composite, iterations )
```

## **FUNCTION**

The composite measure function is meant for measurement function that derive their measurements from the results of other measurement functions. The measurement functions this function is based on is obtained by calling the compose function (FeatureComposeFunction). The composite measure function obtains the results of these measurements through its composite function parameter. Use the regular measurement structure access method to read the values in this parameter (i.e. MeasurementObjectValue).

## **ARGUMENTS**

Data type	Name	Description	
dip_Measurement	measurement	nent Measurement data structure	
$\mathtt{dip}_{-}\mathtt{int}$	featureID	Measurement function ID	
dip_int	objectID	ID of the object to be measured	
dip_Measurement	composite	Measurement structure containing the measurement	
		data this function is based on	
dip_int	iterations	Number of iterations the measure function needs to	
		scan the data	

## SEE ALSO

MeasurementFeatureRegister, FeatureLineFunction, FeatureImageFunction, FeatureChainCodeFunction, FeatureCreateFunction, FeatureComposeFunction

## FeatureConvertFunction

Measurement feature #convert function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureConvertFunction) ( in, featureID, inID, out, outID,
resources )
```

## **FUNCTION**

The convert function should convert the measurement data of the feature feaureID for the object inID in the measurement in to object outID of measurement out. This function is called by MeasurementFeatureConvert.

## **ARGUMENTS**

Data type	Name	Description	
dip_Measurement	in	Input measurement data structure	
dip_int	featureID	Measurement function ID	
dip_int	inID	ID of the object in in	
dip_Measurement	out	Output measurement data structure	
$\mathtt{dip}_{-}\mathtt{int}$	outID	ID of the object in out	
dip_Resources	resources	Resources tracking structure. See ResourcesNew	

## SEE ALSO

## FeatureCreateFunction

Measurement feature #create function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureCreateFunction) ( measurement, featureID, label,
intensity, physDims, params, data, resources )
```

## **FUNCTION**

The create function is called to initialise the measurement function. It should allocate and initialise a memory block for internal use, assign this block to the pointer \*data, and register it in resources.

## **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement feature function ID
dip_Image	label	Image with pixel intensities represending
		object IDs
dip_Image	intensity	Image containing corresponding intensity
		values
dip_PhysicalDimensions	physDims	Physical dimensions data structure
void *	params	For future expansion, is currently always
		NULL
void **	data	Pointer to a data block that can later be
		accessed using MeasurementObjectData
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

## FeatureDescriptionFree

Free a Feature Description

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_FeatureDescriptionFree ( description )
```

## **FUNCTION**

This function frees a Feature Description data structure. This is not the preferred way of freeing a Feature Description. Use the resources mechanism instead (Resources tracking structure. See ResourcesNew).

## **ARGUMENTS**

Data type	Name	Description
dip_FeatureDescription *	description	Feature Description to be freed

## **SEE ALSO**

## FeatureDescriptionFunction

Measurement feature #description function

191

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureDescriptionFunction) ( measurement, featureID,
physDims, decription, resources )
```

## **FUNCTION**

The description function should return a dip\_FeatureDescription structure containing information on the measurement function, such as its name, a short description, labels for each value measured, and units of its measurement. This function is called by MeasurementFeatureDescription.

The description structure should be allocated by this function using FeatureDescriptionNew, and registered in resources. The functions FeatureDescriptionSetName, FeatureDescriptionSetDescription, FeatureDescriptionSetDimensionLabels and FeatureDescriptionSetUnits should be used to populate the structure.

## **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
dip_PhysicalDimensions	physDims	Physical dimensions data structure
dip_FeatureDescription *	description	Pointer to a structure containing
		descriptive information of the
		measurement feature function
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

## **SEE ALSO**

## FeatureDimension

Measure the object's dimensions

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureDimensionID ( void )
```

## **FUNCTION**

dip\_FeatureDimensionID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the length of an object along the principal axes of the label image (e.g. the length object along the X, Y & Z axes).

## SEE ALSO

## Measure

## FeatureExcessKurtosis

Undocumented measurement function

#### **FUNCTION**

This measurement function is undocumented and not meant for public use. Measure

## FeatureFeret

Measure the object's Feret diameters

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureFeretID ( void )
```

#### **FUNCTION**

dip\_FeatureFeretID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the Feret maximum and minimum diameters of an object. The Feret diameter are found by rotating the object's chain code. The default angle stepsize is defined by DIP\_MSR\_FERET\_ACCURACY (set to 0.5 degrees). This measurement function supports a measurement parameter (see Measure), which is defined in dip\_measurement.h. If a non-zero pointer to a dip\_FeretParameters structure is supplied, the structure's stepsize parameter is used instead of the default angle stepsize. Furthermore the structure's angles boolean parameter specifies whether the angles of the Feret diameters should be measured as well. This function supports 2D images only.

## **ARGUMENTS**

Data type	Name	Description
dip_FeretParameters	*feret	Pointer to a Feret measurement parameters structure
		(not yet implemented)

## NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

## **CREDITS**

The original code on which the current implementation is based, was donated by Gerie van der Heijden.

## **SEE ALSO**

Measure, ImageChainCode, ChainCodeGetFeret

## FeatureGinertia

Measure the object's inertia

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int FeatureGinertiaID ( void )
```

#### **FUNCTION**

dip\_FeatureGinertiaID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia (weighted by its grey values) of an object by calculating the eigenvalues of the object's second order moments tensor. This measure only supports 2D and 3D objects. FeatureGinteria supports a measurement parameter (see Measure). If a pointer to a non-zero boolean is supplied, this function will not only measure the eigenvalues of the second order moments tensor, but also the angles of its eigenvectors.

#### **ARGUMENTS**

Data type	Name	Description
dip_Boolean *	angles	Pointer to a boolean specifying that "eigenangles" should be
		measured (not yet implemented)

#### LITERATURE

"Pratical Handbook on Image Processing for Scientific Applications, chapter 16", Bernd Jahne, CRC Press, 1999.

## SEE ALSO

## FeatureGmu

Measure the object's inertia

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int FeatureGmuID ( void )
```

#### **FUNCTION**

dip\_FeatureGmuID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia (weighted by its grey values) of an object by calculating the object's second order moments tensor. This measure only supports 2D and 3D objects. The output tensor is ordered as follows:

```
2D: xx, xy, yy
3D: xx, xy, xz, yy, yz, zz
```

## **LITERATURE**

"Mechanics", Florian Scheck, Springer, 1999.

## **SEE ALSO**

#### Measure

## FeatureGravity

209

Measure the object's gravity

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureGravityID ( void )
```

## **FUNCTION**

dip\_FeatureGravityID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the point of gravity of the object, by calculating the object's first moment weighted by the intensity of each object pixel.

## SEE ALSO

## Measure

## FeatureImageFunction

Measurement feature #measure function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureImageFunction) ( measurement, featureID, label,
intensity, objectID, iterations )
```

## **FUNCTION**

The image measurement function is meant for measurement operation that need neighborhood or global object shape information for its operation (e.g. the FeatureSurfaceArea function needs to evaluate the 6 connected neighborhood of each boundary voxel). The object ID image label can contain values that are not present in objectID. These labels should be ignored.

## **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
$\mathtt{dip}_{-}\mathtt{Image}$	label	Image with pixel intensities represending object IDs
$\mathtt{dip}_{-}\mathtt{Image}$	intensity	Image containing corresponding intensity values
dip_IntegerArray	objectID	Array of objectIDs to be measured
dip_int	iterations	Number of iterations the measure function needs to
		scan the image

## SEE ALSO

#### Measure

## FeatureLineFunction

Measurement feature #measure function

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureLineFunction) ( measurement, featureID, label,intensity, size, objectID, dim, iterations )
```

## **FUNCTION**

The line measure function obtains two arrays (label and intensity) with label and intensity information of the objects to be measured. The line measurement function is called for every line in the image (the scan dimension is determined at run time to be optimal). Since label can contain more than one different label, line itself is responsible for storing the measurement results for the appropriate object (using, for example, MeasurementObjectData). The object ID array label can contain values that are not present in objectID. These labels should be ignored.

## **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
$\mathtt{dip}_{-}\mathtt{int}$	featureID	Measurement function ID
dip_sint32 *	label	Pointer to a list (image line) of object IDs
dip_float *	intensity	Pointer to a list of corresponding intensity values
dip_int	size	Size of the label and intensity list
dip_IntegerArray	objectID	Array of objectIDs to be measured
dip_int	dim	Dimension of the line, see ScanFrameWork
dip_int	iterations	Number of iterations the measure function needs to
		scan the line

## SEE ALSO

#### **FUNCTION**

This measurement function is undocumented and not meant for public use.

NOTE: this function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

#### Measure

## FeatureMass

Measure the mass of the object (sum of grey-values)

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureMassID ( void )
```

#### **FUNCTION**

dip\_FeatureMassID returns the ID value of this measurement function, that is registered by Initialise. This function is just an alias for dip\_FeatureSumID.

This function measures the sum of the grey-value in the intensity image (see Measure) of pixels inside the object, and is equivalent to FeatureSum

## SEE ALSO

## Measure

## FeatureMaximum

Measure the object's maximum coordinate value

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureMaximumID ( void )
```

## **FUNCTION**

dip\_FeatureMaximumID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the maximum coordinate value of each dimension of the object.

## **SEE ALSO**

#### Measure

## FeatureMaxVal

Measure the object's maximum intensity

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureMaxValID ( void )
```

## **FUNCTION**

dip\_FeatureMaxValID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the maximum intensity in the intensity image (see Measure) of pixels inside the object.

## SEE ALSO

## Measure

DIP*lib* function reference 217

## FeatureMean

Measure the object's mean intensity

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureMeanID ( void )
```

#### **FUNCTION**

dip\_FeatureMeanID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the mean intensity in the intensity image (see Measure) of pixels inside the object.

#### SEE ALSO

#### Measure

## FeatureMinimum

Measure the object's minimum coordinate value

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureMinimumID ( void )
```

#### **FUNCTION**

dip\_FeatureMinimumID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the minimum coordinate value of each dimension of the object.

#### **SEE ALSO**

#### Measure

DIP*lib* function reference 219

## FeatureMinVal

Measure the object's minimum intensity

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureMinValID ( void )
```

#### **FUNCTION**

dip\_FeatureMinValID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the minimum intensity in the intensity image (see Measure) of pixels inside the object.

#### SEE ALSO

#### Measure

#### FeatureMu

Measure the object's inertia

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int FeatureMuID ( void )
```

#### **FUNCTION**

dip\_FeatureMuID returns the ID value of this measurement function, that is registered by Initialise.

This function calculates the inertia of an object by calculating the object's second order moments tensor. This measure only supports 2D and 3D objects. The output tensor is ordered as follows:

```
2D: xx, xy, yy3D: xx, xy, xz, yy, yz, zz
```

#### **LITERATURE**

"Mechanics", Florian Scheck, Springer, 1999.

#### SEE ALSO

#### Measure

## FeatureOrientation2D

221

Undocumented measurement function

#### **FUNCTION**

This measurement function is undocumented and not meant for public use. Measure

## FeatureP2A

Measure the circularity of the object

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureP2AID ( void )
```

#### **FUNCTION**

dip\_FeatureP2AID returns the ID value of this measurement function, that is registered by Initialise.

This function is a composite measurement function, that uses FeatureSize,
FeaturePerimeter, and FeatureSurfaceArea to determine the circularity of an object by
calculating: 2D: P2A = perimeter^2 / (4Pi \* size) 3D: P2A = surface-area^1.5 /
(6 Sqrt(Pi) \* size)

#### **NOTE**

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

#### SEE ALSO

#### Measure

## FeaturePerimeter

Measure the object's perimeter length

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeaturePerimeterID ( void )
```

#### **FUNCTION**

dip\_FeaturePerimeterID returns the ID value of this measurement function, that is registered by Initialise.

This measures the perimeter of 2D objects by calculating the length of the chain code of its enclosing border. This function assumes that each object has a single connected border. The used method for measuring the length of the chain code is optimal for circles, and for a collection of objects that are randomly orientated, see the referenced literature for details.

#### NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

# FeatureShape

Measure shape parameters of the object

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureShapeID ( void )
```

#### **FUNCTION**

dip\_FeatureShapeID returns the ID value of this measurement function, that is registered by Initialise.

This function is a composite measurement function, that uses FeatureSize,
FeaturePerimeter, and FeatureFeret to measures the following shape characteristics of
2D objects:

```
Squarity = area / ( s * sp )

Circularity = area / ( Pi/4 * sp^2 )

Triangularity = area / ( 2 * s * sp )

Ellipsity = area / ( Pi/4 * s * sp )

Elongation = p / l
```

with area the size, s the shortest Feret diameter, l the longest Feret diameter, sp the Feret diameter perpendicular to s, and p the perimeter of the object.

When the measured object is either a perfect square, circle, triangle or ellipse, the values obtained by FeatureShape will be 1.0.

#### NOTE

This function uses chain codes. It expects each measured object to be compact, that is, to have only one chain code. Additional chain codes are ignored, meaning that non-compact objects are not measured properly. Take care in providing the correct connectivity value: if you object is compact only with 2-connectivity, this measure will fail if you call Measure with a value of 1 for the connectivity.

## FeatureSize

Measure the object's size

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureSizeID ( void )
```

#### **FUNCTION**

dip\_FeatureSizeID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the object's size by counting the number of pixels having the same object ID. This measure is the optimal procedure for estimating the area (2D) or volume (3D) of an object with an arbitrary size. The measurement value's unit are in pixels (pixels^2 in 2D, pixels^3 in 3D).

#### **SEE ALSO**

#### Measure

## FeatureSkewness

Undocumented measurement function

#### **FUNCTION**

This measurement function is undocumented and not meant for public use. Measure

## FeatureStdDev

Measure the standard deviation of the object's intensity

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureStdDevID ( void )
```

#### **FUNCTION**

dip\_FeatureStdDevID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the standard deviation of the intensity in the intensity image (see Measure) of pixels inside the object.

#### SEE ALSO

#### Measure

#### FeatureSum

Measure the sum of the grey values of the object

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureSumID ( void )
```

#### **FUNCTION**

dip\_FeatureSumID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the sum of the grey-value in the intensity image (see Measure) of pixels inside the object.

#### SEE ALSO

#### Measure

## FeatureSurfaceArea

Measure the area of the object's surface

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_int dip_FeatureSurfaceAreaID ( void )
```

#### **FUNCTION**

dip\_FeatureSurfaceAreaID returns the ID value of this measurement function, that is registered by Initialise.

This function measures the area of a 3D object's surface using six-connected boundary voxels.

## FeatureValueFunction

Measurement feature #value function

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error (*dip_FeatureValueFunction) ( measurement, featureID, objectID,
physDims, data, format, resources )
```

#### **FUNCTION**

The value function should return the measurement values produced by the measurement function, for one specific object. This function is called by MeasurementObjectValue.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
dip_int	objectID	ID of the object to be measured
dip_PhysicalDimensions	physDims	Physical dimensions data structure
void **	data	Pointer to a measurement-specific
		internal data block
dipf_MeasurementValueFormat *	format	Pointer to a data format label, See
		MeasurementObjectValue
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

# FillBoundaryArray

Fill the border of array according to the boundary condition

#### **SYNOPSIS**

dip\_Error DIP\_TPI\_FUNC(dip\_FillBoundaryArray)( in, out, size, border, boundary)

#### **FUNCTION**

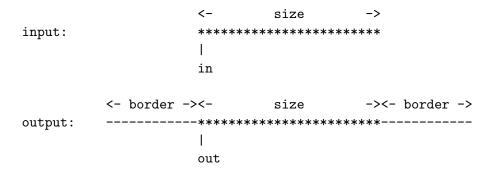

Set the values of the border pixels of an array. The pixels of out outside the range of the array in are set to a value determined by the boundary condition and the pixel values of in.

#### **ARGUMENTS**

Data type	Name	Description
void *	in	input array
void *	out	output array
$\mathtt{dip}_{-}\mathtt{int}$	size	size of input array
dip_int	border	size of the extended borders
dip_Boundary	boundary	Boundary conditions

#### NOTE

The out array has to be allocated before this function is called, and should at least has the size of (size + 2 \* border). Thus, border specifies the length of the border on both sides of the in array. Furthermore, the out pointer should point to that element in the out array that corresponds to the first element in the in array:

The enumerator dip\_boundary contains the following constants:

Name	Description	
DIP_BC_SYM_MIRROR	Symmetric mirroring	
DIP_BC_ASYM_MIRROR	Asymmetric mirroring	
DIP_BC_PERIODIC	Periodic copying	
DIP_BC_ASYM_PERIODIC	Asymmetric periodic copying	
DIP_BC_ADD_ZEROS	Extending the image with zeros	
DIP_BC_ADD_MAX_VALUE	Extending the image with +infinity	
DIP_BC_ADD_MIN_VALUE	Extending the image with -infinity	

# SEE ALSO

SeparableFrameWork

#### FindShift

Estimate the shift between images

#### **SYNOPSIS**

```
#include "dip_findshift.h"
dip_Error dip_FindShift ( in1, in2, out, method, parameter )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

This function estimates the (sub-pixel) global shift between in1 and in2. The numbers found represent the shift of in1 with respect to in2, or the position of the first pixel of in2 in the coordinate system of in1. There are two methods that can be used: CPF and MTS. Both methods require that the shift be small. Therefore, first the integer pixel is calculated, and both images are cropped to the common part.

If method is 0, DIP\_FSM\_MTS is used. method can also be DIP\_FSM\_INTEGER\_ONLY. Integer shifts can be calculated for images of any dimensionality.

#### **CPF**

The CPF method (marked as FFTS in the literature below) uses the phase of the cross-correlation (as calculated by CrossCorrelationFT) to estimate the shift. parameter sets the amount of frequencies used in this estimation. The maximum value that makes sense is sqrt(1/2). Any larger value will give the same result. Choose smaller values to ignore the higher frequencies, which have a smaller SNR and are more affected by aliasing. If parameter is set to 0, the optimal found for images sub-sampled by a factor four will be used (parameter = 0.2).

This method only supports 2-D images (until further notice).

#### **MTS**

The MTS method (marked as GRS in the literature below) uses a first order Taylor approximation of the equation in1(t) = in2(t-s) at scale parameter. Setting parameter to zero, a scale of 1 will be used. This means that the images will be smoothed with a Gaussian kernel of 1. This is the more accurate one of the two methods, and therefore is the

default.

This method supports images with a dimensionality between 1 and 3.

#### **ITER**

The ITER method is an iterative version of the MTS method. It is known that a single gradient based shift estimation have bias due to truncation of the Taylor expansion series (see Pham et.al.) The bias can be expressed as a polynomial of the subpixel displacements. As a result, if Taylor method is applied iteratively and the shift is refined after each iteration, the bias eventually become negligible. By using just 3 iterations, it is possible to correct bias that results in high precision O(1e-6).

#### **PROJ**

The PROJ method compute shift in each dimension from images' projections. It is fast and fairly accurate for high SNR. Should not be used for low SNR

#### **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in1	Input image
dip_Image	in2	Input image
dip_FloatArray	out	Estimated shift
dipf_FindShiftMethod	method	Estimation method
dip_float	parameter	Parameter

The dipf\_FindShiftMethod enumeration consists of the following flags:

Name	Description
DIP_FSM_DEFAULT	Default method (MTS)
DIP_FSM_INTEGER_ONLY	Find only integer shift
DIP_FSM_CPF	Use cross-correlation method
DIP_FSM_FFTS	Same
DIP_FSM_MTS	Use Taylor series method
DIP_FSM_GRS	Same

## FiniteDifference

A linear gradient filter

#### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_FiniteDifference ( in, out, boundary, processDim, filter )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

The FiniteDifference filter implements several basic one dimensional FIR convolution filters. The dimension in which the operation is to be performed is specified by processDim. The operation itself is selected with filter. The  $(1\ 0\ 1)/2$ ,  $(1\ -1\ 0)$  &  $(0\ 1\ -1)$  are difference filters that approximate a first order derivative, the  $(1\ -2\ 1)$  filter approximates a second order derivative operation. The triangular  $(1\ 2\ 1)/4$  filter is a local smoothing filter. All filters are normalized (sum of filter coeff. is 0 or 1).

### **ARGUMENTS**

Data type	Name	Description
${ t dipImage}$	in	Input image
dip_Image	out	Output image
dip_BoundaryArray	boundary	Boundary conditions
dip_int	processDim	ProcessDim
dipf_FiniteDifference	filter	Filter selection

The dipf\_FiniteDifference enumeration consists of the following flags:

Name	Description
DIP_FINITE_DIFFERENCE_M101	out[ii] = (in[ii+1] - in[ii-1])/2
DIP_FINITE_DIFFERENCE_OM11	out[ii] = in[ii+1] - in[ii]
DIP_FINITE_DIFFERENCE_M110	$\operatorname{out}[ii] = \operatorname{in}[ii] - \operatorname{in}[ii-1]$
DIP_FINITE_DIFFERENCE_1M21	out[ii] = in[ii-1] - 2*in[ii] + in[ii+1]
DIP_FINITE_DIFFERENCE_121	out[ii] = (in[ii-1] + 2*in[ii] + in[ii+1])/4

# SEE ALSO

## FiniteDifferenceEx

A linear gradient filter

#### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_FiniteDifferenceEx ( in, out, boundary, process, parOrder,
smoothflag )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

The FiniteDifferenceEx filter implements several basic one dimensional FIR convolution filters. The difference between this function and FiniteDifference is that this one has an interface more similar to Gauss and Derivative: it can process different derivatives along different dimensions at the same time. The first derivative is a convolution with  $(1\ 0\ -1)/2$ , and the second derivative is a convolution with  $(1\ -2\ 1)$ . When parOrder is 0 for a dimension, either the triangular smoothing filter  $(1\ 2\ 1)/4$  is applied (smoothflag set to DIP\_TRUE), or the dimension is not processed at all (smoothflag set to DIP\_FALSE).

Setting all process to DIP\_TRUE, all parOrder to 0 except 1 dimension to 1, and smoothflag to DIP\_TRUE yields the SobelGradient.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	process	Dimensions to process
dip_IntegerArray	parOrder	Order of Derivative along each dimension
dip_Boolean	smoothflag	Wether or not to smooth in the non-derivative
		directions

## FourierTransform

247

Computes the Fourier transform

#### **SYNOPSIS**

```
#include "dip_transform.h"
dip_Error dip_FourierTransform ( in, out, trFlags, process, theFuture )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

Performs a Fourier transform on in and places the result in out.

Normalisation: 1/sqrt(dimension) for each dimension.

Defaults: process may be zero, indicating that all dimensions should be processed.

Sampling in Fourier Domain (FD): Let one pixel in the spatial domain (SD) be Delta\_SD [m], then one pixel in the FD is Delta\_FD =  $1/(Delta\_SD * N)$  [m^-1], where N is the width of the image in pixels. As a consequence the maximal frequency in the FD image is N/2 \*  $1/(Delta\_SD * N) = 1/(2 * Delta\_SD)$  [m^-1] and is thus independent of the image width N and only related to the Nyquist frequency. The frequency of one FD pixel is therefore related to the image width N.

Note: In consequence of the above the FD resolution will not be isotropic if the image size are not square.

Note: Spatial zero-padding of the image increases the FD resolution only apparently (empty magnification).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
$dip_{-}Image$	out	Output
dipf_FourierTransform	trFlags	Transform flags
dip_BooleanArray	process (0)	Dimensions to process

## FTGaussian

Generates the Fourier transform of a Gaussian

### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_FTGaussian ( output, sigma, volume, cutoff )
```

### DATA TYPES

Output: sfloat, scomplex

## **FUNCTION**

Generates the Fourier transform of a Gaussian with sigma's sigma. (The Fourier transform of a Gaussian, is a Gaussian.) volume is the integral of the Gaussian in the spatial domain. The cutoff variable can be used to avoid the calculation of the exponent of large negative values, which is can be very time consuming. Values of the exponent that are below cutoff yield a 0 value for the exponent. When cutoff is set to 0 or a positive value, DIP\_GENERATION\_EXP\_CUTOFF is used (it is defined as -50).

### **ARGUMENTS**

Data type	Name	Description	
$\mathtt{dip}_{-}\mathtt{Image}$	output	Output Image	
dip_FloatArray	sigma	Sigma of the Gaussian	
dip_float	volume	Total intensity of the Gaussian	
dip_float	cutoff	Cutoff value for the exponent	

### **SEE ALSO**

FTEllipsoid, FTSphere, FTBox, FTCube, FTCross

# FTSphere

Generated Fourier transform of a sphere

### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_FTSphere ( image, radius, amplitude )
```

### DATA TYPES

Output: sfloat, scomplex

## **FUNCTION**

Generates the Fourier transform of a sphere with radius radius and an amplitude of amplitude.

### **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	image	Output Image
dip_float	radius	Radius
dip_float	amplitude	Amplitude

### **KNOWN BUGS**

This function is only implemented for images with a dimensionality up to three.

### **SEE ALSO**

FTEllipsoid, FTBox, FTCube, FTCross, FTGaussian

# GaborIIR

Infinite impulse response filter

## **SYNOPSIS**

```
#include "dip_iir.h"
dip_Error dip_GaborIIR ( in, out, boundary, ps, sigmas, frequencies, order,
truncation )
```

### DATA TYPES

binary, integer, float

## **FUNCTION**

Recursive infinite impulse response implementation of the Gabor filter.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	ps	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_FloatArray	frequencies	frequencies
dip_IntegerArray	order	order
dip_float	truncation	Truncation

## **SEE ALSO**

#### GaussIIR

### Gauss

Gaussian Filter

### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_Gauss ( in, out, boundary, process, sigmas, order, truncation )
```

### DATA TYPES

binary, integer, float

### **FUNCTION**

Finite impulse response implementation of a Gaussian convolution filter and Gaussian derivative convolution filters.

The Gaussian kernel is cut off at truncation times the sigma of the filter (in each dimension). The sum of the Gaussian's coefficients is normalised to one. A truncation of zero or less indicates that the global preferred truncation ought to be used, see GlobalGaussianTruncationSet. For the derivatives, the trunction value is increased slightly: the actual value for truncation used is truncation + 0.5\*order. The minimum filter size is 3 pixels, or 5 pixels for the 3rd order derivative.

Both the process and the order parameter may be zero. If process is zero all dimensions are processed. If order is zero no derivatives are taken.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	process (0)	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_IntegerArray	order (0)	Order of Derivative along each dimension
dip_float	truncation (<0)	Truncation of Gaussian

# LIMITATIONS

The order of the derivative is limited to the interval 0-3. Sigmas considerably smaller than 1.0 will yield nonsensical results.

# SEE ALSO

See sections 9.4, "Smoothing operations", and 9.5, "Derivative-based operations", in Fundamentals of Image Processing.

General information about convolution

GaussFT, GaussIIR, Derivative, GlobalGaussianTruncationSet

## GaussFT

Gaussian Filter through the Fourier Domain

### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_GaussFT ( in, out, sigmas, order, truncation )
```

### DATA TYPES

binary, integer, float, complex

### **FUNCTION**

Fourier Domain implementation of a Gaussian convolution filter and Gaussian derivative convolution filters. The Gaussian kernel in the Fourier Domain is cut off at the equivalent of truncation times sigmas. If truncation is smaller or equal to 0, it is cut off where the argument to exp is smaller than -50, as in FTGaussian.

The order parameter may be zero, in which case no derivatives are taken.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_FloatArray	sigmas	Sigma of Gaussian
dip_IntegerArray	order (0)	Order of Derivative along each dimension
dip_float	truncation	Truncation of Gaussian kernel

### **SEE ALSO**

See sections 9.4, "Smoothing operations", and 9.5, "Derivative-based operations", in Fundamentals of Image Processing.

General information about convolution

Gauss, GaussIIR, Derivative

## GaussianNoise

Generate an image disturbed by Gaussian noise

### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_GaussianNoise ( in, out, variance, random )
```

### DATA TYPES

integer, float

### **FUNCTION**

Generate an image disturbed by additive Gaussian noise. See GaussianRandomVariable for more information on the random number generator.

### **ARGUMENTS**

Data type	Name	Description	
dip_Image	in	Input	
dip_Image	out	Output	
dip_float	variance	Variance of the Gaussian distribution the noise is drawn	
		from	
dip_Random *	random	Pointer to a random value structure	

### **EXAMPLE**

Get a image with additive Gaussian noise as follows:

```
dip_Image in, out;
dip_float variance;
dip_Random random;

variance = 1.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_GaussianNoise( in, out, variance, &random ));
```

# SEE ALSO

 ${\tt Gaussian Random Variable, Random Variable, Random Seed, Random Seed Vector, } \\ {\tt Uniform Noise, Poisson Noise, Binary Noise}$ 

## GaussianRandomVariable

Gaussian random variable generator

### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_GaussianRandomVariable ( random, mean, variance, output1,
output2 )
```

### **FUNCTION**

GaussianRandomVariable uses the algorithm described by D.E. Knuth as the Polar Method to generate two Gaussian distributed random variables. See RandomVariable for more information on the random number generator.

#### **ARGUMENTS**

Data type	Name	Description	
dip_Random *	random	Pointer to a random value structure	
dip_float	mean	Mean of the distribution, the samples are drawn from	
dip_float	variance	Variance of the distribution, the samples are drawn from	
dip_float *	output1	First output value	
dip_float *	output2	Second output value	

### **EXAMPLE**

Get two Gaussian random variable as follows:

```
dip_Random random;
dip_float mean, variance, value1, value2;

mean = 0.0;
variance = 1.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_GaussianRandomVariable( &random, mean, variance, &value1, &value2 ));
```

# GaussianSigma

Adaptive Gaussian smoothing filter

#### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_GaussianSigma ( in, out, boundary, sigma, gaussSigma,
outputCount, truncation )
```

### DATA TYPES

integer, float

### **FUNCTION**

The GaussianSigma filter is an adaptive Gauss-ian smoothing filter. The value of the pixel under investigation is replaced by the Gaussian-weighted average of the pixelvalues in the filter region which lie in the interval +/- 2 sigma from the value of the pixel that is filtered. The filter region is specified by gaussSigma and truncation. If outputCount is DIP\_TRUE, the output values represent the number of pixel over which the average has been calculated. When threshold is DIP\_TRUE, the pixel intensities are being thresholded at +/- 2 sigma, when it is set to DIP\_FALSE, the intensities are weighted with the Gaussian difference with the intensity of the central pixel.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_BoundaryArray	boundary	Boundary conditions
dip_float	sigma	Sigma
dip_FloatArray	gaussSigma	Sigma of Gaussian
dip_Boolean	outputCount	Output the Count
dip_float	truncation (-1.0)	Truncation of Gaussian

## GaussIIR

Infinite impulse response filter

## **SYNOPSIS**

```
#include "dip_iir.h"
dip_Error dip_GaussIIR ( in, out, boundary, process, sigmas, order,
truncation )
```

### DATA TYPES

binary, integer, float

## **FUNCTION**

Recursive infinite impulse response implementation of the Gauss filter.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	process	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_IntegerArray	order	Order of Derivative
dip_IntegerArray	order	Order of the IIR Filter
dip_int	designMethod	Method of IIR design
dip_float	truncation	Truncation of Gaussian

## GeneralisedKuwahara

Generalised Kuwahara filter

269

### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_GeneralisedKuwahara ( in, selection, out, se, boundary,
filterSize, shape, minimum )
```

### DATA TYPES

binary, integer, float

### **FUNCTION**

This function is a generalisation of the Kuwahara filter in the sense that is does not use the variance criterion to select the smoothed value, but instead accepts an image with the selection values. The algorithm finds, for every pixel, the minimum or maximum (as specified with minimum) value of selection within the filter window (its size specified by filterSize).

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	selection	Selection
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterSize	Filter sizes
dip_FilterShape	shape	Filter shape
dip_Boolean	minimum	Minimum

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

# SEE ALSO

Get

Get a pixel value

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_Get ( in, const, cor, adjust )
```

### **FUNCTION**

This functions get the value of a pixel in image in at the coordinate cor. If cor is zero, the first pixel value is retrieved.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_Image	const	0-D output image
dip_IntegerArray	cor	Pixel coordinate
dip_Boolean	adjust	Adjust data type of output image

# **SEE ALSO**

 ${\tt GetInteger,\,GetFloat,\,GetComplex,\,dip\_PixelGetInteger,\,dip\_PixelGetFloat,\,Set}$ 

# GetComplex

Get complex pixel value

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_GetComplex ( in, value, cor )
```

### **FUNCTION**

This functions get the value of a pixel in image in at the coordinate cor. If cor is zero, the first pixel value is retrieved.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_complex *	value	Value
dip_IntegerArray	cor	Pixel coordinate

## **SEE ALSO**

Get, GetInteger, GetFloat, dip\_PixelGetInteger, dip\_PixelGetFloat, Set

273

# GetFloat

Get float pixel value

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_GetFloat ( in, value, cor )
```

### **FUNCTION**

This functions get the value of a pixel in image in at the coordinate cor. If cor is zero, the first pixel value is retrieved.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_float *	value	Value
dip_IntegerArray	cor	Pixel coordinate

## **SEE ALSO**

Get, GetInteger, GetComplex, dip\_PixelGetInteger, dip\_PixelGetFloat, Set

# GetInteger

Get integer pixel value

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_GetInteger ( in, value, cor )
```

### **FUNCTION**

This functions get the value of a pixel in image in at the coordinate cor. If cor is zero, the first pixel value is retrieved.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_int *	value	Value
dip_IntegerArray	cor	Pixel coordinate

## **SEE ALSO**

Get, GetFloat, GetComplex, dip\_PixelGetInteger, dip\_PixelGetFloat, Set

# ${\tt GetLibraryInformation}$

Support function

### **SYNOPSIS**

```
#include "dip_information.h"
dip_Error dip_GetLibraryInformation ( info )
#include "dipio_image.h"
dip_Error dipio_GetLibraryInformation ( info )
```

### **FUNCTION**

This function fills the given dip\_LibraryInformation structure with information about the release version and date, copyright information and author information of the DIPlib library.

## **ARGUMENTS**

Data type	Name	Description
dip_LibraryInformation*	info	DIPlib library information

## GetLine

Get a line from an image

### **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_GetLine ( in, out, cor, dimension )
```

### DATA TYPES

binary, integer, float, complex

### **FUNCTION**

Get a orthogonal line form an image. The position of the line in the image is specified by the coordinates at which its left most pixel (cor) should be placed and on which dimension of the image, the dimension of the line maps (dimension). If in has If in has a different type than out, it will be converted to the type of out.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in Input Image	
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output Line Image
dip_IntegerArray	cor	Coordinate in the image of the left most pixel of the
		line
dip_int	dimension	Dimension of the image on which the line's dimension
		maps

### **SEE ALSO**

GetSlice, PutSlice, PutLine

# GetMaximumAndMinimum

statistics function

277

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_GetMaximumAndMinimum ( in, mask, max, min )
```

### DATA TYPES

integer, float

### **FUNCTION**

This function gets both the maximum and minimum of all the pixel values in the in image. Optionally, a mask image can be specified to exclude pixels from this search.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input image
dip_Image	mask (0)	Mask image
dip_float	*max	Pointer to maximum variable
dip_float	*min	Pointer to minimum variable

### **SEE ALSO**

Maximum, Minimum

# GetObjectLabels

Lists object labels in image

### **SYNOPSIS**

dip\_Error dip\_GetObjectLabels ( in, mask, labels, nullIsObject, resources )

### DATA TYPES

binary, integer

### **FUNCTION**

This function produces an array of object labels present in the image in. Optionally, mask can mask the regions in in where to search for labels. The boolean nullIsObject specifies whether or not to treat the value zero as an object label.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input label image
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask image
dip_IntegerArray *	labels	Array of labels
dip_Boolean	nullIsObject	treat the value zero ad an object label
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

Label, IntegerArrayFind

## GetRank

Value selection function

### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_GetRank ( array, datatype, min, max, rank, value )
```

### **FUNCTION**

GetRank gets the value at rank rank in the array array. min should be set to the first index of array, max to the last. dip\_GetRank will use array for temporary storage, so the values in the array will be changed are this function is ready.

### **ARGUMENTS**

Data type	Name	Description	
dip_float *	array	Array to searched in	
dip_DataType	datatype		
dip_int	min	minimal array index	
$\mathtt{dip}_{-}\mathtt{int}$	max	maximal array index	
$\mathtt{dip}_{-}\mathtt{int}$	rank	Rank	
dip_float *	value	Value of the rank element	

## **EXAMPLE**

This example finds the median value for the array.

```
dip_float array[ SIZE ], median;
dip_int rank;

/* fill the array with values */

rank = SIZE/2;
DIPXX( dip_GetRank( array, DIP_DT_FLOAT, 0, (SIZE - 1), rank, &median ));
```

# GetSlice

Get a slice from an image

### **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_GetSlice ( in, out, cor, dim1, dim2 )
```

### DATA TYPES

binary, integer, float, complex

### **FUNCTION**

Get a orthogonal slice from a image. The requested slice is selected by specifying its upper left corner (cor) and on which dimensions of the image, the dimensions of the slice map (dim1, dim2). If in has a different type than out, it will be converted to the type of out.

### **ARGUMENTS**

Data type	Name	Description	
dip_Image	in	3D Input Image	
$\mathtt{dip}_{-}\mathtt{Image}$	out	2D Output Image	
dip_IntegerArray	cor	Coordinate in in of the upper left corner of the slice	
dip_int	dim1	Dimension of in on which the slice's first dimension maps	
dip_int	dim2	Dimension of in on which the slice's second	
		dimensionmaps

# GetUniqueNumber

Obtain an unique value

## **SYNOPSIS**

```
#include "dip_globals.h"
dip_Error dip_GetUniqueNumber ( number )
```

### **FUNCTION**

This function gives an unique integer value. The value is unique is the sense that its value has not yet been returned by this function nor will it be returned by subsequent calls.

## **ARGUMENTS**

Data type	Name	Description
dip_int *	number	Pointer to an integer in which the number is stored

# ${\tt Global Boundary Condition Get}$

Get global Boundary Conditions

### **SYNOPSIS**

```
#include "dip_globals.h"
dip_Error dip_GlobalBoundaryConditionGet ( boundary, size, resources )
```

### **FUNCTION**

This function allocates the boundary array array of size size with the global default boundary conditions for each dimension of the image. The initial values of this global array is DIP\_BC\_SYMMETRIC\_MIRROR.

### **ARGUMENTS**

Data type	Name	Description
dip_BoundaryArray *	boundary	Pointer to Boundary conditions
dip_int	size	Size of the new array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# GradientDirection2D

Derivative filter

## **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_GradientDirection2D ( in, out, boundary, ps, sigmas, tc,
atanFlavour, flavour )
```

## DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float** 

## **FUNCTION**

Computes the gradient direction of an image using the <code>Derivative</code> function. This functions supports only two dimensional images.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	ps	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_float	tc	Truncation of Gaussian
dip_GradientDirectionAtanFlavour	atanFlavour	Atan flavour
dip_DerivativeFlavour	flavour	Derivative flavour

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

## Greater

293

Compare grey values in two images

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Greater ( in1, in2, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function sets each pixel in out to "true" when for corresponding pixels in1 > in2. This is the same as Compare with the DIP\_SELECT\_GREATER selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in1	First input
dip_Image	in2	Second input
dip_Image	out	Output

## **SEE ALSO**

Compare, Threshold, Equal, Lesser, NotEqual, NotGreater, NotLesser, SelectValue, NotZero

## GreyWeightedDistanceTransform

Grey weighted distance transform

#### **SYNOPSIS**

```
#include "dip_distance.h"
dip_Error dip_GreyWeightedDistanceTransform ( in, seed, out, distance, chamfer, neighborhood, metric )
```

#### DATA TYPES

in: integer, float
seed: binary

#### **FUNCTION**

GreyWeightedDistanceTransform determines the grey weighted distance transform of the object elements in the in image and returns the result in the out image. The implemented algorithm uses a heap sort for sorting the pixels to be processed.

The images in and seed must have the same dimensions. The out image will be converted to a sfloat typed image. The seed image defines the elements that are part of the object for which the GDT is determined. It can be any type of image where all image elements not equal to 0 are considered to be part of the object(s). Those elements that are neighboring an object element in the output image are considered seeds. Before any seeds are detected the borders of the out image are set to 0. The size of the border is determined by the chamfer metric size (see below). In case of a 3 by 3 chamfer metric the image border is one element, in case of a 5 by 5 chamfer it is 2 elements. Elements in the border are not considered seeds. If no valid seeds are found the routine will terminate with an Illegal value error code.

The chamfer metric is defined by two parameters: neighborhood and metric. neigborhood should supply the different relative addresses of the neighboring elements according to the chamfer metric. The first element neighborhood[0] contains the number of elements in the chamfer neighborhood. The next three elements contain the maximum number of elements a chamfer metric exceeds the central element. The rest of the elements (starting from the fifth element) contain addresses of the different chamfer elements relative to the central element. The metric array contains the corresponding chamfer metric value. An example of a 3x3 neighborhood array with the corresponding metric is:

```
neighborhood[0] = 8 (number of elements)
neighborhood[1] = 1 (x-border size)
neighborhood[2] = 1 (y-border size)
```

```
neighborhood[3] = 0 (z-border size)
neighborhood[4] = -imagewidth - 1,
                                      metric[0] = 7
neighborhood[5] = -imagewidth,
                                      metric[1] = 5
                                      metric[2] = 7
neighborhood[6] = -imagewidth + 1,
neighborhood[7] = -1,
                                      metric[3] = 5
neighborhood[8] = 1,
                                      metric[4] = 5
neighborhood[9] = imagewidth - 1,
                                      metric[5] = 7
neighborhood[10] = imagewidth,
                                      metric[6] = 5
                                      metric[7] = 7
neighborhood[11] = imagewidth + 1,
```

where imagewidth represents the width of the image in image pixels. If both neighborhood and metric pointers are NULL, the chamfer variable can be set to either 1 (indicating a 3x3 or 3x3x3 chamfer using only 4 or 6 direct neighbors), 3 (indicating a 3x3 or 3x3x3 chamfer, using all neighbors) or 5 (indicating a 5x5 or 5x5x5 chamfer). In these cases a preset neighborhood and metric arrays will be used.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	seed	Seed image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Integrated grey-value over least-resistance path
		(output image)
$dip_{-}Image$	distance	Metric distance over least-resistance path (output
		image)
dip_int	chamfer	Chamfer distance metric
dip_IntegerArray	neighborhood	Neighborhood
dip_FloatArray	metric	Metric

## **KNOWN BUGS**

GreyWeightedDistanceTransform works only on 2 or 3-dimensional images. It will not work if any of the images has different strides.

GreyWeightedDistanceTransform does not process pixels in a 2-pixel border around the edge. If this is an issue, consider adding 2 pixels on each side of your image.

The function <code>GrowRegionsWeighted</code> produces a grey-weighted distance transform without these limitations and with some other possibilities.

## GrowRegions

Dilate the regions in a labelled image

#### **SYNOPSIS**

```
#include "dip_regions.h"
dip_Error dip_GrowRegions ( in, grey, mask, out, connectivity, iterations, order )
```

## DATA TYPES

in: binary, integer

grey: interger, float (converted to dip\_sfloat)

mask: dip\_uint8

#### **FUNCTION**

The regions in the input image in are grown with several options:

If grey is NULL, the regions are dilated iterations steps, according to connectivity (see The connectivity parameter), and optionally constrained by mask. This is the labelled equivalent to BinaryPropagation. If iterations is 0, the objects are dilated until no further change is possible. order is ignored.

If an image grey is given, the labels are grown in order of the grey-values in grey. order indicates whether pixels with high grey-values are added first or last. iterations is ignored, and mask is an optional constraint. This is a watershed algorithm with initial labels. The function Watershed does not accept an initial segmentation, so these two functions complement each other. Note that GrowRegions does not leave any watershed pixels in between the regions.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input binary or labelled image
dip_Image	grey	Input grey-value image
dip_Image	mask	Mask image
dip_Image	out	Output binary or labelled image
dip_int	connectivity	Connectivity
dip_int	iterations	Number of iterations
dipf_GreyValueSortOrder	order	Whether to grow from low to high or high
		to low

The  ${\tt dipf\_GreyValueSortOrder}\ enumeration\ consists\ of\ the\ following\ values:$ 

Name	Description
DIP_GVSO_HIGH_FIRST	Process the pixels from high grey-value to low grey-value.
DIP_GVSO_LOW_FIRST	Process the pixels from low grey-value to high grey-value.

## **SEE ALSO**

GrowRegionsWeighted, Watershed, BinaryPropagation, Label

# GrowRegionsWeighted

Grow labelled regions using grey-weighted distances

#### **SYNOPSIS**

```
#include "dip_regions.h"
dip_Error GrowRegionsWeighted ( in, grey, mask, out, distance, pixelsize, chamfer, metric )
```

#### DATA TYPES

in: binary, integer

grey: interger, float (converted to dip\_sfloat)

mask: dip\_uint8

#### **FUNCTION**

The regions in the input image in are grown according to a grey-weighted distance metric; the weights are given by grey. The optional mask image mask limits the growing. out contains the grown regions, and distance, if not 0, contains the grey-weighted distance of each pixel in mask to the nearest pixel in in. Non-isotropic sampling is supported through pixelsize, which can be set to 0 to assume isotropic sampling. chamfer selects the size of the chamfer metric: 3 or 5. Set chamfer to 0 to use a custom metric given by the image metric. This image should be odd in size, and each pixel gives the distance to the center pixel. The pixels set to 0 will not be considered as neighbors.

The chamfer metric used is the following for chamfer==3 (with ps0=pixelsize->array[0] and ps1=pixelsize->array[1]):

sqrt(ps0*ps0+ps1*ps1)	ps1	sqrt(ps0*ps0+ps1*ps1)
ps0	0	ps0
sqrt(ps0*ps0+ps1*ps1)	ps1	sqrt(ps0*ps0+ps1*ps1)

and the following for chamfer==5:

0		0		0	
	sqrt(ps0*ps0+4	*ps1*ps1)	sqrt(ps0*ps0+4	*ps1*ps1)	
		ps1			
sqrt(4*ps0*ps0+pss/r*p/sp/s)0*ps0+ps1*ps1)		sqrt(ps0*ps0+p	s1 <b>seps</b> t104*ps0*ps0	+ps1*ps1)	
0	ps0	0	ps0	0	
		ps1			
sqrt(4*ps0*ps0+psspr*p(spts))*ps0+ps1*ps1)		sqrt(ps0*ps0+p	s1 <b>s4ps</b> t104*ps0*ps0	+ps1*ps1)	
0		0		0	
	sqrt(ps0*ps0+4	*ps1*ps1)	sqrt(ps0*ps0+4	*ps1*ps1)	

Setting chamfer to 0 and metric to an image with these values produces the same results as setting chamfer to 3 or 5.

The output image distance is comparable to the out image of GreyWeightedDistanceTransform, except that that function uses optimal chamfer distances whereas this one uses the (sub-optimal) true distance. In return, this function works on images of any dimensionality, allows for non-isotropic sampling, does not skip pixels close to the edge of the image, and can be used with a mask image to constrain the propagation. Note that the seed image in GreyWeightedDistanceTransform corresponds to the zero pixels of in for this function.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input binary or labelled image
$\mathtt{dip}_{-}\mathtt{Image}$	grey	Input grey-value image
dip_Image	mask	Mask image
dip_Image	out	Output binary or labelled image
dip_Image	distance	Output distance image
dip_FloatArray	pixelsize	Pixel size
dip_int	chamfer	Chamfer distance
dip_Image	metric	Custom metric

## HartleyTransform

301

Computes the Hartley transform

#### **SYNOPSIS**

```
#include "dip_transform.h"
dip_Error dip_HartleyTransform ( in, out, trFlags, process )
```

#### DATA TYPES

binary, integer, float

### **FUNCTION**

This function computes a Hartley transform on in and places the result in out.

Normalisation: 1/sqrt(dimension) for each dimension.

The main advantage of the Hartley transform over the Fourier transform is that is requires half the storage for real valued images. Note, that is also possible to directly reduce the storage requirements of the Fourier transform by just storing the right half plane, since for real valued images the left half plane can be derived from the right half using the symmetry properties of the Fourier transform.

Unfortunately there seem to be two definitions of the multi-dimensional Hartley transform (they are identical in the 1-D case). DIPlib implements the Bracewell (see below) variant, since this one is easy to implement and inherits the storage advantage from the 1-D case. The following are references which each use a different variant (all scaling factors have been dropped):

Bracewell, "Discrete Hartley Transform", J. Opt. Soc. Am, vol. 73, no. 12, December 1983:

$$DHT(u,v) = Sum Sum I(x,y) cas(ux) cas(vy)$$

$$y x$$

Kenneth R. Castleman, "Digital image processing", Prentice Hall, 1996:

$$DHT(u,v) = Sum Sum I(x,y) cas(ux + vy)$$

$$y x$$

Using cas(a) = cos(a) + sin(a):

cas(ux)cas(vy) = cos(ux)cos(vy)+cos(ux)sin(vy)+sin(ux)cos(vy)+sin(ux)sin(vy)

```
cas(ux+vy) = cos(ux)cos(vy)+cos(ux)sin(vy)+sin(ux)cos(vy)-sin(ux)sin(vy)
```

A subtle difference. The two definitions have very similar properties, for example the convolution property.

In implementation terms, Bracewell is equivalent to perform the one-dimensional Hartley transform along each dimension. The Castleman variant is equivalent to the definition: DHT = re(DFT) - im(DFT). On a final note, I've not noticed mention of the difference between the two variants, so the indications Bracewell's and Castleman's variant are not and should not be accepted "labels" to refer to the variants (For both variants I have selected the first reference I came across, not chronologically the first reference to use the variant).

Defaults: process may be zero, indicating that all dimensions should be processed.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dipf_FourierTransform	trFlags	Transformation flags
dip_BooleanArray	process (0)	Dimensions to process

The dipf\_FourierTransform enumeration consists of the following flags:

Name	Description
DIP_TR_FORWARD	Forward transformation
DIP_TR_INVERSE	Inverse transformation

## **SEE ALSO**

FourierTransform

# HasNormalStride

Determines whether an image has a normal stride

## **SYNOPSIS**

dip\_Error dip\_HasNormalStride( image, &answer )

## **FUNCTION**

Determines whether an image has a normal stride. If answer is not zero, the verdict is passed in this variable. Otherwise, HasNormalStride returns an error in case image does not have a normal stride.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	image	The image under investigation
dip_Boolean *	answer	The verdict

## **SEE ALSO**

The image structure

 ${\tt ImageGetStride, IsScalar}$ 

# ${\tt HysteresisThreshold}$

Point Operation

## **SYNOPSIS**

```
#include "dip_point.h"
dip_Error dip_HysteresisThreshold ( in, out, low, high )
```

## DATA TYPES

integer, float

## **FUNCTION**

Performs hysteresis thresholding. From the binary image (in>low) only those regions are selected for which at least one location also has (in>high). The output image will be a binary image with foreground pixel 1 and background pixel 0;

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input image
dip_Image	out	Output image
dip_float	low	Lower threshold
dip_float	high	Higher threshold

## **SEE ALSO**

Threshold, RangeThreshold, IsodataThreshold

## IDivergence

difference measure

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_IDivergence ( in1, in2, mask, out )
```

#### DATA TYPES

binary, integer, float

## **FUNCTION**

Calculates the I-divergence between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

The I-Divergence is defined as:  $I(x,y) = x \ln(x/y) - (x - y)$  and is divided by the number of pixels. It is the -log of a possion distribution  $p(x,y)=e^{-(-y)/x!-y^2}x$  with the stirling approximation for  $\ln x!$ . For x=0, the stirling approximation would fail, y is returned.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in1	First input, Data:x
dip_Image	in2	Second input, Model:y
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask
dip_Image	out	Output

# ImageAssimilate

Inherit properties of another image

## **SYNOPSIS**

dip\_Error dip\_ImageAssimilate( example, target )

## **FUNCTION**

Give the target image the same properties (type, data type, etc...) as the example image. The example image may be either "raw" or "forged". The target image is forged.

If the target was forged before calling this function, and it exactly matches the example, nothing happens. If it doesn't match the example, it is stripped before the properties are copied.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	example	An example image
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	target	The target image

# ImageChainCode

Extracts all chain codes from a labeled image

#### **SYNOPSIS**

```
#include "dip_chaincode.h"
dip_Error dip_ImageChainCode ( objectIm, connectivity, objectID, chaincodearray, resources )
```

### DATA TYPES

## integer

#### **FUNCTION**

Extracts the chain codes for the objects in objectIm (only 2D images supported) that are listed in objectID, assuming that each object is compact (i.e. it returns the chain code for only one border for each label ID in objectID). Chain codes are constructed according to connectivity, which can only be 1 or 2 (see The connectivity parameter). The output structure chaincodearray is allocated by this function and registered in resources.

The dip\_ChainCodeArray structure, like all arrays in DIPlib, contains a size and an array element. Each element is of type dip\_ChainCode, and accessed by chaincodearray->array[ii], where ii is between 0 and chaincodearray->size-1. Data in the dip\_ChainCode structures can only be accessed through the corresponding access functions, see ChainCodeNew.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	objectIm	Labeled input image
dip_int	connectivity	Pixel connectivity of the objects
dip_IntegerArray	objectID	Array containing object label values
dip_ChainCodeArray *	chaincodearray	Output chain codes
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

# ${\tt ImageCopyProperties}$

Copy the properties of an image

## **SYNOPSIS**

dip\_Error dip\_ImageCopyProperties( example, target )

## **FUNCTION**

Give the target image the same properties (type, data type, etc...) as the example image. The example image may be either "raw" or "forged", whereas the target image must be "raw". See ImageAssimilate.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	example	An example image
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	target	The target image

## **SEE ALSO**

The image structure

## ImageFileGetInfo

Get information about image in file (in dipIO)

#### **SYNOPSIS**

dip\_Error dipio\_ImageFileGetInfo ( imInfo, filename, format, addExtensions, recognised, resources )

#### **FUNCTION**

This function opens an image file and fills a dipio\_ImageFileInformation structure with the information from that file. imInfo is allocated by this function. Use ImageFileInformationFree to free this structure, or set the resources parameter for automatic deallocation. If format is 0, all different ImageRead functions are called in sequence until the correct format has been found. If you know the format, get the correct format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats.

The boolean addExtensions specifies whether ImageFileGetInfo should try to add file format extensions to filename, if the registered file format reader fails to recognise filename straight away. The extensions are provided by the registered file readers.

If recognised is not zero, ImageFileGetInfo will set it to DIP\_TRUE when it has been able to read filename, and it will set it to DIP\_FALSE when it is not able to read the file. No error will be generated in this case.

### **ARGUMENTS**

Data type	Name	Description	
$ ext{dipio}_{ ext{-}} ext{ImageFileInformation} *$	imInfo	Output image file information. See	
		ImageFileInformationNew	
dip_String	filename	File name	
dip_int	format	ID of file format	
dip_Boolean	addExtensions	Add file format extensions to	
		filename	
dip_Boolean *	recognised	Pointer to boolean containing the	
		file read status	
dip_Resources	resources	Resources tracking structure. See	
		ResourcesNew

# ImageFileInformationFree

Free a Image File Information structure (in dipIO)

## **SYNOPSIS**

dip\_Error dipio\_ImageFileInformationFree ( imInfo )

## **FUNCTION**

Frees a dipio\_ImageFileInformation structure allocated through ImageFileInformationNew or by ImageFileGetInfo.

## **ARGUMENTS**

Data type	Name	Description
$ ext{dipio}_{-}  ext{ImageFileInformation} *$	imInfo	Structure to free

## **SEE ALSO**

 ${\tt ImageFileInformationNew, ImageFileGetInfo}$ 

# ImageFileInformationNew

Allocate an Image File Information structure (in dipIO)

## **SYNOPSIS**

dip\_Error dipio\_ImageFileInformationNew ( newImInfo, name, filetype,
datatype, dims, resources )

## **FUNCTION**

Allocates a dipio\_ImageFileInformation structure. It must be freed through ImageFileInformationFree, unless a resources parameter is given, in which case it will be freed automatically when freeing the resources. This structure is usually allocated by ImageFileGetInfo.

This function will fill out some of the values in the structure with the values given on the command line. All of these can be 0.

#### **ARGUMENTS**

Data type	Name	Description
dipio_ImageFileInformation *	newImInfo	Output structure
dip_String	name	Initial value for name
dip_String	filetype	Initial value for filetype
dip_DataType	datatype	Initial value for datatype
dip_IntegerArray	dims	Initial value for dimensions
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

The structure dipio\_ImageFileInformation contains the following elements:

Data type	Name	Description
dip_String	name	File name
dip_String	filetype	File format string
dip_DataType	datatype	Data type of image
dip_int	sigbits	Significant bits
$ exttt{dip\_IntegerArray}$	dimensions	Dimensions of image
dipio_PhotometricInterpretation	photometric	Color space
dip_PhysicalDimensions	physDims	Physical dimensions structure.
		See PhysicalDimensionsNew
dip_int	numberOfImages	Number of images in a TIFF
		file. If filetype is not
		"TIFF", this number is not set
dip_StringArray	history	History tags
dip_Resources	resources	Resource tracking; all elements
		within this structure are
		tracked here

The enumerator  ${\tt dipio\_PhotometricInterpretation}$  contains the following constants:

Name	Description		
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.		
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)		
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)		
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)		
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)		
DIDIO DIM GIELIN	,		
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)		
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a*		
	and b*)		
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)		
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)		
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and		
	value)		
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and		
	value)		
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE		
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as		
	DIPIO_PHM_CMYK		

Most file formats support only some of these.

## **SEE ALSO**

 ${\tt ImageFileInformationFree}, {\tt ImageFileGetInfo}, {\tt PhysicalDimensionsNew}$ 

# ImageForge

Allocate pixel data for an image

## **SYNOPSIS**

dip\_Error dip\_ImageForge( image )

## **FUNCTION**

Allocates a block of memory to store pixel data for an image. The image must be "raw", and will be "forged" afterwards. The routine will fail if the image fields do not contain a valid combination of values for the image type.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	image	The image for which the pixel data must be allocated

## **SEE ALSO**

The image structure

ImageNew, ImageFree, ImageStrip, ImageCopyProperties

# ImageFree

Free an image

#### **SYNOPSIS**

dip\_Error dip\_ImageFree( image )

## **FUNCTION**

Free any pixel data associated with the image and return all fields to their initial ("raw") state by calling <code>ImageStrip</code>. Then the image structure itself is freed. Notice that you must pass a pointer to the image instead of the image itself. This allows <code>ImageFree</code> to set your image variable to zero, preventing further use of the now freed image.

Because ImageNew accepts a resources structure to keep track of allocated images, direct calls to ImageFree should be unnecessary.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image *	image	A pointer to the image to be freed

## **SEE ALSO**

The image structure

## ImageGetData

Get the data pointers of a set of images

#### **SYNOPSIS**

```
dip_Error dip_ImageGetData( in, idp, iflags, out, odp, oflags, flags,
resources )
```

#### **FUNCTION**

Get the data pointers of a set of images. This function should not be called before the clean up of the previous invocation (by ResourcesFree) has been performed. Currently no clean up is required by ImageGetData, but any data pointers obtained by a previous call to this function should be considered invalid when calling this function. The iflags, oflags, and flags parameters are not used in the current version. These fields should be set to zero. The resources parameter is mandatory. Any of the image arrays' elements may be set to zero, indicating that it is to be ignored.

No functions that will possibly modify an image should be called after the call to ImageGetData and before its clean up. The proper time to call ImageGetPlane and ImageGetStride is right after the call to ImageGetData.

## **ARGUMENTS**

Data type	Name	Description
dip_ImageArray in		Array of input images
<pre>dip_VoidPointerArray *</pre>	idp	Returns input data pointers
${ t dipf\_ImageGetDataArray}$	iflags	Flags for input images
$ exttt{dip\_ImageArray}$	out	Array of output images
dip_VoidPointerArray *	odp	Returns output data pointers
${ t dipf\_ImageGetDataArray}$	oflags	Flags for output images
${ t dipf\_ImageGetData}$	flags	Flags for all images
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

## **SEE ALSO**

The image structure

ImageGetPlane, ImageGetStride

# ${\tt ImageGetDataType}$

Read the data type field

## **SYNOPSIS**

dip\_Error dip\_ImageGetDataType( image, dataType )

## **FUNCTION**

Read the dip\_Image data type field.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	An image
dip_DataType *	dataType	Returns the data type field

## **SEE ALSO**

The image structure DIPlib's data types ImageSetDataType

# ${\tt ImageGetDimensionality}$

Read the dimensionality field

## **SYNOPSIS**

dip\_Error dip\_ImageGetDimensionality( image, dimensionality )

## **FUNCTION**

Read the dip\_Image dimensionality field.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	image	An image
dip_int *	dimensionality	Returns the dimensionality field

## **SEE ALSO**

The image structure

 ${\tt ImageGetDimensions}$ 

# ${\tt ImageGetDimensions}$

Read the dimensions array

327

### **SYNOPSIS**

dip\_Error dip\_ImageGetDimensions( image, dimensions, resources )

### **FUNCTION**

Read the dip\_Image dimensions Array. The array that is used to return the dimensions in, is allocated by this routine using IntegerArrayNew.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	image	An image
dip_IntegerArray *	dimensions	Returns the dimensions Array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

The image structure

 ${\tt ImageGetDimensionality}$ 

# ImageGetPlane

Read the plane number

### **SYNOPSIS**

dip\_Error dip\_ImageGetPlane( image, plane )

### **FUNCTION**

Read the dip\_Image plane number. For binary images this is the number of the bit in which the data is stored. For other data types it is meaningless. The proper time to call this function is right after ImageGetData.

### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	image	An image
dip_Int *	plane	Returns the plane number

## SEE ALSO

The image structure

 ${\tt ImageGetData, ImageGetStride}$ 

# ${\tt ImageGetStride}$

Read the stride array

### **SYNOPSIS**

dip\_Error dip\_ImageGetStride( image, &stride, resources )

### **FUNCTION**

Read the dip\_Image stride array. The array that is used to return the dimensions in, is allocated by this routine using IntegerArrayNew. The proper time to call this function is right after ImageGetData.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	An image
dip_IntegerArray *	stride	Returns the stride array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

### **SEE ALSO**

The image structure

ImageGetData, ImageGetPlane

# ImageGetType

Read the type field

## **SYNOPSIS**

dip\_Error dip\_ImageGetType( image, type )

## **FUNCTION**

Read the  ${\tt dip\_Image}$  type field.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	image	An image
<pre>dip_ImageType *</pre>	type	Returns the type field

DIPlib function reference

# ImageIsGIF

Confirm that a file is a GIF file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_gif.h"
dip_Error dipio_ImageIsGIF ( filename, veredict )
```

### **FUNCTION**

This function verifies that the file is an GIF file. veredict is set to DIP\_TRUE if it is, and to DIP\_FALSE if it isn't.

### **ARGUMENTS**

Data type	Name	Description
dip_String	filename	File name
dip_Boolean *	veredict	Set to DIP_TRUE or DIP_FALSE

### **SOFTWARE**

This function uses GifLib (version 4.1.0 or later), which supports GIF 87a & 98a. Copyright (c)1997 Eric S. Raymond

# ImageIsLSM

Confirm that a file is a Zeiss LSM file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_ics.h"
dip_Error dipio_ImageIsLSM ( filename, veredict )
```

### **FUNCTION**

This function verifies that the file is a Zeiss LSM file. veredict is set to DIP\_TRUE if it is, and to DIP\_FALSE if it isn't.

### **ARGUMENTS**

Data type	Name	Description
dip_String	filename	File name
dip_Boolean *	veredict	Set to DIP_TRUE or DIP_FALSE

### **SOFTWARE**

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon Graphics, Inc.

### **SEE ALSO**

# ImageIsTIFF

Confirm that a file is a TIFF file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_tiff.h"
dip_Error dipio_ImageIsTIFF ( filename, veredict )
```

### **FUNCTION**

This function verifies that the file is a TIFF file. veredict is set to DIP\_TRUE if it is, and to DIP\_FALSE if it isn't.

### **ARGUMENTS**

Data type	Name	Description
dip_String	filename	File name
dip_Boolean *	veredict	Set to DIP_TRUE or DIP_FALSE

### **SOFTWARE**

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon Graphics, Inc.

### **SEE ALSO**

ImageWriteTIFF, ImageReadTIFF

# ImageNew

Allocate a structure

### **SYNOPSIS**

dip\_Error dip\_ImageNew( image, resources )

### **FUNCTION**

Allocates a dip\_Image structure and initializes all fields to their default values. The resulting image is in the "raw" state, see The image structure. By using ImageCopyProperties and the "ImageSet" access functions, the image fields can be set to their desired values. Pixel data for the image can be allocated using the ImageForge function, which will will put the image in the "forged" state.

### **ARGUMENTS**

Data type	Name	Description
dip_Image *	image	Used to return the newly allocated image
dip_Resources	resources	Resources tracking structure. See ResourcesNew

### **SEE ALSO**

The image structure

ImageFree, ImageForge, ImageStrip, ImageCopyProperties

## ImageRead

Read grey-value image from file (in dipIO)

#### **SYNOPSIS**

dip\_Error dipio\_ImageRead ( image, filename, format, addExtensions, recognised )

#### **FUNCTION**

This function reads an image from a file and puts it in image. image must be allocated before calling this function. If format is 0, all different ImageRead functions are called in sequence until the correct format has been found. If you know the format, get the correct format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats.

The boolean addExtensions specifies whether ImageRead should try to add file format extensions to filename, if the registered file format reader fails to recognise filename straight away. The extensions are provided by the registered file readers.

If recognised is not zero, ImageRead will set it to DIP\_TRUE when it has been able to read filename, and it will set it to DIP\_FALSE when it is not able to read the file. No error will be generated in this case.

If the file contains a colour image, Colour2Gray is called. That is, this function always returns a grey-value image.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	image	Output image
$\mathtt{dip}\_\mathtt{String}$	filename	File name
$\mathtt{dip}_{-}\mathtt{int}$	format	ID of file format
dip_Boolean	addExtensions	Add file format extensions to filename
dip_Boolean *	recognised	Pointer to boolean containing the file read status

#### SEE ALSO

ImageReadColour, ImageReadROI, ImageFileGetInfo, ImageReadCSV, ImageReadGIF,
ImageReadICS, ImageReadLSM, ImageReadPIC, ImageReadTIFF, ImageReadJPEG,
ImageWrite, Colour2Gray

## ImageReadColour

Read colour image from file (in dipIO)

### **SYNOPSIS**

dip\_Error dipio\_ImageReadColour ( image, filename, photometric, format, addExtensions, recognised )

#### **FUNCTION**

This function reads an image from a file and puts it in image. image must be allocated before calling this function. It works the same as ImageRead, except that, if the file contains a colour image, Colour2Gray is not called. The returned image has an extra dimension with colours (always the last dimension), and photometric is set to the colour space.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation*	photometric	Photometric interpretation
		(==colour space)
dip_int	format	ID of file format
dip_Boolean	addExtensions	Add file format extensions to
		filename
dip_Boolean *	recognised	Pointer to boolean containing
		the file read status

The enumerator dipio\_PhotometricInterpretation contains the following constants:

DIP*lib* function reference 339

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and
	yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta,
	yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u*
	and $v^*$ )
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a*
	and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and
	value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and
	value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as
	DIPIO_PHM_CMYK

Most file formats support only some of these.

### **SEE ALSO**

# ImageReadCSV

Read comma-separated values from file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_csv.h"
dip_Error dipio_ImageReadCSV ( image, filename, separator )
```

### **FUNCTION**

This function reads the comma-separated values from a file and puts it in image. image must be allocated before calling this function.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	image	Output image
dip_String	filename	File name
char	separator	Separator character

### **SEE ALSO**

ImageRead, ImageWriteCSV

# ${\tt ImageReadCSVInfo}$

Get information about image in comma-separated values file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_csv.h"
dip_Error dipio_ImageReadCSVInfo ( imInfo, filename )
```

### **FUNCTION**

Opens a comma-separated values (CSV) file and fills a dipio\_ImageFileInformation structure with the information from that file. imInfo must be allocated before calling this function.

### **ARGUMENTS**

Data type	Name	Description
dipio_ImageFileInformation imInfo		Output image file information. See
		${\tt ImageFileInformationNew}$
dip_String	filename	File name

### **SEE ALSO**

 ${\tt ImageFileGetInfo,\,ImageReadCSV,\,ImageWriteCSV,\,ImageFileInformationNew}$ 

# ImageReadGIF

Read a GIF image from file (in dipIO)

## **SYNOPSIS**

```
#include "dipio_gif.h"
dip_Error dipio_ImageReadGIF ( image, filename, photometric )
```

### **FUNCTION**

This function reads an image from a GIF file and puts it in image. image must be allocated before calling this function.

### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation *	photometric	Photometric interpretation

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a* and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as DIPIO_PHM_CMYK

Most file formats support only some of these.

### **SOFTWARE**

This function uses  ${\tt GifLib}$  (version 4.1.0 or later), which supports GIF 87a & 98a. Copyright (c)1997 Eric S. Raymond

## ImageReadICS

Read ICS image from file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_ics.h"
dip_Error dipio_ImageReadICS ( image, filename, photometric, offset, roisize,
sampling )
```

### **FUNCTION**

This function reads the image in the ICS file and puts it in image. image must be allocated before calling this function. photometric is set to match the photometric interpretation of the data in the file, if it is recognised. The colour dimension is always the last dimension of the image (no matter how it was saved in the ICS file). offset, roisize and sampling define a ROI to read in. See the comments in ImageReadROI for more information on this.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation*	photometric	Photometric interpretation
dip_IntegerArray	offset	ROI offset
dip_IntegerArray	roisize	ROI size
dip_IntegerArray	sampling	ROI sampling rate

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a* and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as DIPIO_PHM_CMYK

Most file formats support only some of these.

### **SOFTWARE**

This function uses libics (version 1.3 or later), which supports the ICS specification revision 2.0. Copyright (c)2000-2002 Cris L. Luengo Hendriks, Dr. Hans T.M. van der Voort and many others.

## ImageReadJPEG

Read JPEG image from file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_jpeg.h"
dip_Error dipio_ImageReadJPEG ( image, filename, imageNumber, photometric )
```

### **FUNCTION**

This function reads an image from the JPEG file and puts it in image. image must be allocated before calling this function. photometric is set to either DIPIO\_PHM\_RGB or DIPIO\_PHM\_GREYVALUE. If photometric is 0, the image will be read in as grey-value, even if color information is present in the file. Color images are allocated as 3D images, with the different samples along the 3rd. dimension.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation *	photometric	Photometric interpretation

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a* and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as DIPIO_PHM_CMYK

349

Most file formats support only some of these.

## **SOFTWARE**

This function uses libjpeg (version 6b or later). Copyright (c)1994-1998, Thomas G. Lane.

## ImageReadLSM

Read Zeiss LSM image from file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_lsm.h"
dip_Error dipio_ImageReadLSM ( image, filename, offset, roisize, sampling, imInfo, resources )
```

#### **FUNCTION**

This function reads the image in the Zeiss LSM file and puts it in image. image must be allocated before calling this function. Depending on the recording mode and the number of channels recorded, an image with 2 to 5 dimensions is returned. If multiple channels were recorded, they will be put along the last dimension (which can be either the third, fourth or fifth). The "stack", "time series plane" ans "time series z-scan" recording modes return a 3D image, the "time series stack" returns a 4D image, all other modes return a 2D image (including the "line" mode).

imInfo->physDims contains information on the distance between pixels. resources is only used to allocate the imInfo structure, so if imInfo is 0, resources can be 0 too.

offset, roisize and sampling define a region of interest to read in. See the comments in ImageReadROI for more information on this. Note that the channel dimension is part of this ROI.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dip_IntegerArray	offset	ROI offset
dip_IntegerArray	roisize	ROI size
dip_IntegerArray	sampling	ROI sampling rate
dipio_ImageFileInformation*	imInfo	Image file information structure
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

#### **SOFTWARE**

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon

Graphics, Inc.

This function uses  ${\tt zlib}$  (version 1.1.4 or later). Copyright (c)1995-2002 Jean-loup Gailly and Mark Adler

ImageFileGetInfo, ImageIsLSM, ImageReadLSM, ImageFileInformationNew

## ImageReadPIC

Read BioRad PIC image from file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_pic.h"
dip_Error dipio_ImageReadPIC ( image, filename, offset, roisize, sampling, info, resources )
```

### **FUNCTION**

This function reads the image in the BioRAD PIC file and puts it in image. image must be allocated before calling this function. The information stored in the file is put in info.

offset and roisize define a region of interest to be read in. The ROI is clipped to the actual image data, so it is safe to specify a ROI that is too large. sampling can be used to read in a subset of the pixels of the chosen ROI. Any or all of these three parameters can be NULL.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dip_IntegerArray	offset	ROI offset
dip_IntegerArray	roisize	ROI size
dip_IntegerArray	sampling	ROI sampling rate
dipio_ImageFileInformation *	info	File information
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

```

### **FUNCTION**

Opens a BioRAD PIC file and fills a dipio\_ImageFileInformation structure with the information from that file. imInfo must be allocated before calling this function.

### **ARGUMENTS**

Data type	Name	Description
${\tt dipio\_ImageFileInformation}$	imInfo	Output image file information. See
		${\tt ImageFileInformationNew}$
dip_String	filename	File name

### **SEE ALSO**

ImageFileGetInfo, ImageReadPIC, ImageFileInformationNew

## ImageReadROI

Read a portion of a grey-value image from file (in diplO)

#### **SYNOPSIS**

dip\_Error dipio\_ImageReadROI ( image, filename, offset, roisize, sampling, format, addExtensions, recognised )

#### **FUNCTION**

This function reads an image from a file and puts it in image. image must be allocated before calling this function. It works the same as ImageRead, except that the user is allowed to specify a region of the image to read. This is done through the offset and roisize parameters. The ROI is clipped to the image size, so it is safe to specify a ROI that is too large. sampling can be used to read in a subset of the pixels of the chosen ROI. Any or all of these three parameters can be NULL.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	image	Output image
dip_String	filename	File name
dip_IntegerArray	offset	ROI offset
dip_IntegerArray	roisize	ROI size
dip_IntegerArray	sampling	ROI sampling rate
$\mathtt{dip}_{-}\mathtt{int}$	format	ID of file format
dip_Boolean	addExtensions	Add file format extensions to filename
dip_Boolean *	recognised	Pointer to boolean containing the file read status

### **SEE ALSO**

ImageRead, ImageReadColour, ImageFileGetInfo, ImageReadCSV, ImageReadGIF, ImageReadICS, ImageReadLSM, ImageReadPIC, ImageReadTIFF, ImageReadJPEG, ImageWrite, Colour2Gray

# ${\tt ImageReadTIFF}$

Read TIFF image from file (in dipIO)

### **SYNOPSIS**

```
#include "dipio_tiff.h"
dip_Error dipio_ImageReadTIFF ( image, filename, imageNumber, photometric )
```

### **FUNCTION**

This function reads an image from the TIFF file and puts it in image. image must be allocated before calling this function. imageNumber indicates which image from the multi-page TIFF file to read. 0 is the first image. photometric is set to match the photometric interpretation of the TIFF file. Color images and multi-sample images are allocated as 3D images, with the different samples along the 3rd. dimension.

#### **ARGUMENTS**

Data type	Name	Description
$ ext{dip}_{-} ext{Image}$	image	Output image
dip_String	filename	File name
dip_int	imageNumber	Image number to read
dipio_PhotometricInterpretation *	photometric	Photometric interpretation

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a* and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as DIPIO_PHM_CMYK

Most file formats support only some of these.

### **SOFTWARE**

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon Graphics, Inc.

This function uses zlib (version 1.1.4 or later). Copyright (c)1995-2002 Jean-loup Gailly and Mark Adler

### **KNOWN BUGS**

TIFF is a very flexible file format. We have to limit the types of images that can be read to the more common ones, and to the ones dipIO writes. These are the most obvious limitations:

Tiled images are not supported.

Only 1, 4, 8, 16 and 32 bits per pixel integer grayvalues are read, as well as 32-bit and 64-bit floating point.

Only 4 and 8 bits per pixel colourmapped images are read. Colourmapped images contain 16-bit gray-values: stretching of the display will be necessary.

Class Y images (YCbCr) and Log-compressed images (LogLuv or LogL) are not supported.

$\sim$		_	Λ	 $\sim$	$\overline{}$
S	<b>-</b>	ь.	Α	2	( )

 ${\tt ImageReadColour, ImageWriteTIFF, ImageIsTIFF, Colour2Gray}$ 

## ImageReadTIFFInfo

Get information about image in TIFF file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_tiff.h"
dip_Error dipio_ImageReadTIFFInfo ( imInfo, filename, imageNumber )
```

### **FUNCTION**

Opens a TIFF file and fills a dipio\_ImageFileInformation structure with the information from that file. imInfo must be allocated before calling this function. imageNumber indicates which image from the multi-page TIFF file to get info on. 0 is the first image. imInfo->numberOfImages gives the number of pages in the file.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dipio\_ImageFileInformation}$	imInfo	Output image file information. See
		ImageFileInformationNew
dip_String	filename	File name
dip_int	imageNumber	Image number to query

#### **SOFTWARE**

This function uses libtiff (version 3.6.1 or later), which supports the TIFF specification revision 6.0. Copyright (c)1988-1997 Sam Leffler and Copyright (c)1991-1997 Silicon Graphics, Inc.

# ImagesCheck

Check properties of several images

#### **SYNOPSIS**

dip\_Error dip\_ImagesCheck( images, imageType, dataType, compareFlag, checkFlag )

#### **FUNCTION**

This function checks whether the image type and the data type of the first image in the array matches with the imageType and dataType variables, and compares the other image fields of the first image with those of the other images in the array. This comparison is done by calling ImagesCompareTwo. The checkFlag can be used to compare properties not supported by ImagesCompare. An error is returned by ImagesCheck if a check or comparison fails.

#### **ARGUMENTS**

Data type	Name	Description
dip_ImageArray *	images	Array of Images
${\tt dip\_ImageType}$	imageType	Image type of the first Image
dip_DataTypeProperties	dataType	Data type of the first Image. See
		DataTypeGetInfo
dipf_ImagesCompare	compareFlag	Properties to compare. See ImagesCompare
dipf_ImagesCheck	checkFlag	Extra properties to be compared

#### dipf\_ImagesCheck

Name	Description
DIP_CKIM_MAX_PRECISION_MATCH	Check whether data types match or match to the
	DIP_GTP_MAX_PRECISION DataType
DIP_CKIM_CASTING_TYPE_MATCH	Check whether data types match or match to the
	DIP_GTP_CAST_R2C or DIP_GTP_CAST_C2R types of
	the first image in image
DIP_CKIM_IGNORE_NULL_DIM_IMAGES	Ignore images with a zero dimensionality, this flag
	is usefull when 0d images are used as generic data
	containers of constants

SEE ALSO

 ${\tt ImagesCompareTwo,\,ImagesCompare,\,ImagesCheckTwo}$ 

# ImagesCheckTwo

Check properties of two images

#### **SYNOPSIS**

dip\_Error dip\_ImagesCheckTwo( image1, image2, imageType, dataType, compareFlag, checkFlag )

#### **FUNCTION**

This function checks whether the image type and the data type of the first DIPlib Image matches with the imageType and dataType variables, and compares the other Image fields of the first DIPlib Image with those of the second Image. This comparison is done by calling ImagesCompareTwo. The checkFlag can be used to compare properties not supported by ImagesCompare. ImagesCheckTwo returns an error code if a check or comparison fails.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image1	First Image
${\tt dip\_Image}$	image2	Second Image
${\tt dip\_ImageType}$	imageType	Image type of the first Image
dip_DataTypeProperties	dataType	Data type of the first Image. See
		DataTypeGetInfo
dipf_ImagesCompare	compareFlag	Properties to compare. See ImagesCompare
${ t dipf\_ImagesCheck}$	checkFlag	Extra properties to be compared

#### $dipf_{-}ImagesCheck$

Name	Description
DIP_CKIM_MAX_PRECISION_MATCH	Check whether data types match or match to the
	DIP_GTP_MAX_PRECISION DataType
DIP_CKIM_CASTING_TYPE_MATCH	Check whether data types match or match to the
	DIP_GTP_CAST_R2C or DIP_GTP_CAST_C2R types
DIP_CKIM_IGNORE_NULL_DIM_IMAGES	Ignore images with a zero dimensionality, this flag
	is usefull when 0d images are used as generic data
	containers of constants

SEE ALSO

 ${\tt ImagesCompareTwo,\ ImagesCompare,\ ImagesCheck}$ 

## ImagesCompare

Compare properties of several images

#### **SYNOPSIS**

dip\_Error dip\_ImagesCompare( images, condition, result )

#### **FUNCTION**

This function compares some standard fields of a number of Images or performs a full comparison. Only if the comparison result is true between each of the Images, will the final comparison result be true. The condition parameter specifies which properties should be tested. If 0, a full comparison of the Images is performed. Otherwise it should be a logical OR of the dipf\_ImagesCompare flags. DIP\_CPIM\_MATCH\_ALL\_STANDARD is equivalent to all the flags OR'ed together. The difference between DIP\_CPIM\_MATCH\_ALL\_STANDARD and the full comparison specified by 0, is that the first will compare all the standard fields ( type, data type, dimensions ), whereas the other compares all fields relevant to a particular DIPlib Image type. This may exclude some of the standard fields and include some fields particular to the type of DIPlib Image in question. There are two modes of operation. If the result parameter is set, it is used to store the result of the comparison, a set of OR'ed dipf\_ImagesCompare flags. If the result parameter is 0, an error is returned if the condition parameter and the resulting set of flags are not the same.

#### **ARGUMENTS**

Data type	Name	Description
$ extstyle{dip\_ImageArray}$	images	Array of Images
dipf_ImagesCompare	condition	Properties to compare. 0 indicates full
		comparison
dipf_ImagesCompare *	result	Result: flags to indicate if the properties were the
		same. 0 indicates that an error should be
		returned if the requested properties do not match

# $dipf\_ImagesCompare$

Name	Description
DIP_CPIM_DIMENSIONALITIES_MATCH	Dimensionalities match
DIP_CPIM_DIMENSIONS_MATCH	Dimensions match. The comparison is done up to
	the lower of the of the two dimensionalities
DIP_CPIM_SIZE_MATCH	Combination of
	DIP_CPIM_DIMENSIONALITIES_MATCH and
	DIP_CPIM_DIMENSIONS_MATCH
DIP_CPIM_TYPES_MATCH	Types match
DIP_CPIM_DATA_TYPES_MATCH	Data types match
DIP_CPIM_MATCH_ALL_STANDARD	All flags above OR'ed together
DIP_CPIM_STRIDES_MATCH	Strides match
DIP_CPIM_FULL_MATCH	Full match. Returned in result. To test for a full
	match use 0. <b>Note:</b> This is NOT equivalent to the
	other flags OR'ed together, and it cannot be used
	as condition

# SEE ALSO

 ${\tt ImagesCompareTwo,\,ImagesCheckTwo,\,ImagesCheck}$ 

# ImagesCompareTwo

Compare properties of two images

#### **SYNOPSIS**

dip\_Error dip\_ImagesCompareTwo( image1, image2, condition, result )

#### **FUNCTION**

This function compares some standard fields of two Images or performs a full comparison. The condition parameter specifies which properties should be tested. See ImagesCompare for more information. There are two modes of operation. If the result parameter is set, it is used to store the result of the comparison, a set of OR'ed dipf\_ImagesCompare flags. If the result parameter is 0, an error is returned if the condition parameter and the resulting set of flags are not the same.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image1	First Image
$\mathtt{dip}_{-}\mathtt{Image}$	image2	Second Image
dipf_ImagesCompare	condition	Properties to compare. See ImagesCompare
dipf_ImagesCompare*	result	Result: flags to indicate if the properties were the
		same. 0 indicates that an error should be returned
		if the requested properties do not match

DIPlib function reference

# ${\tt ImageSort}$

Sort image data

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_ImageSort ( in, out, algorithm )
```

#### **FUNCTION**

Produces an image (out) with the sorted pixel values of in.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
dip_Sort	algorithm	Sort algorithm

The sortType parameter is one of:

Name	Description
DIP_SORT_DEFAULT	Default sort algorithm
DIP_SORT_QUICK_SORT	Quick sort
DIP_SORT_DISTRIBUTION_SORT	Distribution sort
DIP_SORT_INSERTION_SORT	Insertion sort

#### **SEE ALSO**

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, SortIndices, SortIndices16, ImageSortIndices}$ 

# ${\tt ImageSortIndices}$

Sort indices to image data

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_ImageSortIndices ( in, indices, algorithm, flags )
```

#### **FUNCTION**

Sorts a list of indices rather than the data itself using the algorithm specified by algorithm. Unless the DIP\_ISI\_USE\_INDICES, the indices image will be initialised with one index for each pixel in the image.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	indices	Indices
dip_Sort	algorithm	Sort algorithm
${ t dipf_{-}ImageSortIndices}$	flags	Flags

The sortType parameter is one of:

Name	Description
DIP_SORT_DEFAULT	Default sort algorithm
DIP_SORT_QUICK_SORT	Quick sort
DIP_SORT_DISTRIBUTION_SORT	Distribution sort
DIP_SORT_INSERTION_SORT	Insertion sort

The dipf\_ImageSortIndices enumeration consists of the following flags:

Name	Description
DIP_ISI_USE_INDICES	Use the indices as given in the indices image

#### **SEE ALSO**

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, ImageSort, SortIndices, SortIndices16}$ 

# ImagesSeparate

Take care of in-place operations

#### **SYNOPSIS**

dip\_Error dip\_ImagesSeparate( in, out, newOut, saved, resources )

#### **FUNCTION**

First the list of output images is checked to see if any output image is used more than once. If this is the case an error is returned. Then the input and output images are examined. If any of the output images is also used as an input image, the function allocates a new image. This image is returned through the newOut array. For each output image a corresponding image is returned in this array. Either the original output image itself, or either a new image as discussed above. After the call to dip\_ImagesSeparate, the images in the newOut array should be used instead of the original output images. After you are done processing the images, a call to ResourcesFree will perform the necessary post-processing. The post-processing consists of copying the data from the temporary output images to the original output images and freeing the temporary images. Because the post-processing is called through ResourcesFree, the resources parameter is mandatory. Any of the image arrays' elements may be set to zero, indicating that it is to be ignored.

The boolean saved array can be used to indicate that an input image has been stored in a safe place. In this case dip\_ImagesSeparate will not have to allocate a temporary image if the input image is also used as an output image. The saved parameter may either be zero, which indicates that none of the input images has been saved, or it must be an array containing booleans corresponding each of the input images. DIP\_TRUE indicates that the image has been saved.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\scriptscriptstyle{-}}\mathtt{ImageArray}$	in	An array of input images
dip_ImageArray	out	An array of output images
dip_ImageArray *	newOut	Returns an array containing the replacement output
		images
dip_BooleanArray	saved	An array of booleans indicating which input images
		are safely stored
dip_Resources	resources	Resources tracking structure. See ResourcesNew. May
		not be zero

# ${\tt ImageStrip}$

375

Restore an image to its initial ("raw") state

#### **SYNOPSIS**

dip\_Error dip\_ImageStrip( image )

#### **FUNCTION**

Free any pixel data associated with the image and return all fields to their initial ("raw") state. Essentially the image is returned to the state it was in right after it was allocated with ImageNew.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	image	The image to be stripped

#### **SEE ALSO**

The image structure

ImageNew, ImageForge, ImageFree, ImageCopyProperties

# ImageWrite

Write grey-value image to file (in dipIO)

#### **SYNOPSIS**

dip\_Error dipio\_ImageWrite ( image, filename, physDims, format, compression )

#### **FUNCTION**

This function writes a grey-vlaue image to a file, overwriting any other file with the same name. physDims gives physical dimensions of the image, and can be set to 0 for default values. Not all file formats are able to store physical dimensions. Get the format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats. If format is 0, ICSv2 is used.

#### **ARGUMENTS**

Data type	Name Description	
${\tt dip\_Image}$	image	Output image
dip_String	filename File name	
dip_PhysicalDimensions	physDims Physical dimensions structure. See	
		PhysicalDimensionsNew
dip_int	format	ID of file format
dipio_Compression	compression	Compression method and level. See
		Compression methods for image files

#### **SEE ALSO**

ImageWriteColour, ImageWriteCSV, ImageWriteEPS, ImageWriteFLD, ImageWriteGIF, ImageWriteICS, ImageWritePS, ImageWriteTIFF, ImageWriteJPEG, ImageRead

# ImageWriteColour

Write colour image to file (in dipIO)

#### **SYNOPSIS**

dip\_Error dipio\_ImageWriteColour ( image, filename, photometric, physDims, format, compression )

#### **FUNCTION**

This function writes a colour image to a file, overwriting any other file with the same name. photometric must be set to the correct value. Not all file formats support all photometric values, and some don't support colour at all. physDims gives physical dimensions of the image, and can be set to 0 for default values. Not all file formats are able to store physical dimensions. Get the format ID through the registry functions. See File formats recognized by dipIO for a list of currently supported formats. If format is 0, ICSv2 is used.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation	photometric	Photometric interpretation
		(==colour space)
dip_PhysicalDimensions	physDims	Physical dimensions structure.
		See PhysicalDimensionsNew
dip_int	format	ID of file format
dipio_Compression	compression	Compression method and level.
		See Compression methods for
		image files

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a* and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as DIPIO_PHM_CMYK

Most file formats support only some of these.

#### SEE ALSO

ImageWrite, ImageWriteCSV, ImageWriteEPS, ImageWriteFLD, ImageWriteGIF,
ImageWriteICS, ImageWritePS, ImageWriteTIFF, ImageWriteJPEG, ImageRead,
Colour2Gray

# ImageWriteCSV

Write image to a comma-separated-value file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_csv.h"
dip_Error dipio_ImageWriteCSV ( image, filename, separator )
dip_Error dipio_ImageWriteCSV ( dip_Image, dip_String, char );
```

#### **FUNCTION**

This function writes the image to a comma-separated-values file, overwriting any other file with the same name. Optionally, an other separator than the comma can be specified using separator. Sometimes a space, a tab or a colon are used instead. Each line of image data is ended by a newline.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	image	Output image
dip_String	filename	File name
char	separator	Optional alternative separator character

#### **SEE ALSO**

ImageWrite, ImageReadCSV

# ImageWriteEPS

Write image to Encapsulated PostScript file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_ps.h"
dip_Error dipio_ImageWriteEPS ( image, filename, photometric, xcm, ycm, border )
```

#### **FUNCTION**

This function writes the image to an Encapsulated PostScript file, overwriting any other file with the same name. Set the image size in xcm and ycm. border sets the size of the border around the image. If border is 0, no border is drawn. For colour images, set photometric (supported are RGB and CMYK) and write the colour channels along the third image dimension.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation	photometric	Photometric interpretation
dip_float	xcm	X-size of image in cm.
dip_float	ycm	Y-size of image in cm.
dip_int	border	Thickness of border, zero is no
		border

The enumerator  ${\tt dipio\_PhotometricInterpretation}$  contains the following constants:

DIPlib function reference

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u* and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a* and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as DIPIO_PHM_CMYK

Most file formats support only some of these.

## SEE ALSO

ImageWrite, ImageWriteColour, ImageWritePS

# ${\tt ImageWriteFLD}$

Write image to AVS field file (in dipIO)

## **SYNOPSIS**

```
#include "dipio_fld.h"
dip_Error dipio_ImageWriteFLD ( image, filename )
```

## **FUNCTION**

This function writes the image to an AVS Field file.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	image	Output image
dip_String	filename	File name

#### **SEE ALSO**

ImageWrite

# ImageWriteGIF

Write image to a GIF file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_gif.h"
dip_Error dipio_ImageWriteGIF ( image, filename, labelImage )
```

#### **FUNCTION**

This function writes the gray-value image to a GIF file, overwriting any other file with the same name. Optionally, an integer-typed image can be identified as a labeled image using labelImage. In that case a colour GIF image will be saved.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	image	Output image
dip_String	filename	File name
dip_Boolean	labelImage	Regard an integer image as a labeled image

#### **SOFTWARE**

This function uses GifLib (version 4.1.0 or later), which supports GIF 87a & 98a. Copyright (c)1997 Eric S. Raymond

#### **SEE ALSO**

ImageWrite, ImageReadGIF, ImageIsGIF

# ImageWriteICS

Write ICS image to file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_ics.h"
dip_Error dipio_ImageWriteICS ( image, filename, photometric, physDims, history, sigbits, version, compression )
```

#### **FUNCTION**

This function writes the image to an ICS file, overwriting any other file with the same name. version can set to 1 to use the ICS v.1.0 file format (the 2-file version), instead of ICS v.2.0. For colour images, set photometric and write the colour channels along the last image dimension. Set sigbits only if the number of significant bits is different from the full range of the data type of image (use 0 otherwise). physDims can be set to 0 to fill out default values. history can be 0 if you do not want to bother.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation	photometric	Photometric interpretation
dip_PhysicalDimensions	physDims	Physical dimensions structure.
		See PhysicalDimensionsNew
dip_StringArray	history	Tags that are written to the
		history in the ICS header
dip_int	sigbits	Number of significant bits.
dip_int	version	ICS version
dipio_Compression	compression	Compression method and level.
		See Compression methods for
		image files

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta, yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u*
	and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a*
	and b*)
DIPIO_PHM_CIEXYZ   CIE XYZ (the first three planes are X, Y and Z)	
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and
	value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and
	value)
DIPIO_PHM_DEFAULT Same as DIPIO_PHM_GREYVALUE	
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as
	DIPIO_PHM_CMYK

Most file formats support only some of these.

#### **SOFTWARE**

# ImageWriteJPEG

Write JPEG image to file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_jpeg.h"
dip_Error ImageWriteJPEG ( image, filename, photometric, physDims, complevel
)
```

#### **FUNCTION**

This function writes the image to a JPEG file, overwriting any other file with the same name. photometric can set to let the function know how to write the JPEG image (supported colour space is RGB).

If photometric is not DIPIO\_PHM\_GRAYVALUE, a 3D image is expected, in which the different planes are stored along the 3rd dimension.

physDims gives physical dimensions of the image, which will be used to set the dots per inch property of the JPEG file. It can be set to 0 for default values (300 dpi). If the physDims->dimensionUnits is not given, meters are assumed.

complevel is a number between 1 (worst quality, smallest files) and 100 (best quality, largest files). Setting complevel to 0 uses the default compression level, which is 90.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation	photometric	Photometric interpretation
dip_PhysicalDimensions	physDims	Physical dimensions structure.
		See PhysicalDimensionsNew
dipio_uint	complevel	Compression level

The enumerator dipio\_PhotometricInterpretation contains the following constants:

Name	Description
DIPIO_PHM_GREYVALUE	No colour information present; it's a grey-value image.
DIPIO_PHM_RGB	RGB image (the first three planes are red, green and blue)
DIPIO_PHM_RGB_NONLINEAR	Non-linear R'G'B' image (RGB channels to the power of 0.4)
DIPIO_PHM_CMY	CMY image (the first three planes are cyan, magenta and
	yellow)
DIPIO_PHM_CMYK	CMYK image (the first four planes are cyan, magenta,
	yellow and black)
DIPIO_PHM_CIELUV	CIE L*u'v' image (the first three planes are luminosity, u*
	and v*)
DIPIO_PHM_CIELAB	CIE L*a*b* image (the first three planes are luminosity, a*
	and b*)
DIPIO_PHM_CIEXYZ	CIE XYZ (the first three planes are X, Y and Z)
DIPIO_PHM_CIEYXY	CIE Yxy (the first three planes are Y, x and y)
DIPIO_PHM_HCV	HCV image (the first three planes are hue, chroma and
	value)
DIPIO_PHM_HSV	HSV image (the first three planes are hue, saturation and
	value)
DIPIO_PHM_DEFAULT	Same as DIPIO_PHM_GREYVALUE
DIPIO_PHM_GENERIC	Anything can be coded in the channels; the same as
	DIPIO_PHM_CMYK

387

Most file formats support only some of these.

# ImageWritePS

Write image to PostScript file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_ps.h"
dip_Error dipio_ImageWritePS ( image, filename, photometric, caption, xcm,
ycm, border )
```

#### **FUNCTION**

This function writes the image to a PostScript file, overwriting any other file with the same name. Set the image size in xcm and ycm. border sets the size of the border around the image. If border is 0, no border is drawn. You can give the page a title through caption. For colour images, set photometric (supported are RGB and CMYK) and write the colour channels along the third image dimension.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	image	Output image
dip_String	filename	File name
dipio_PhotometricInterpretation	photometric	Photometric interpretation
dip_String	caption	Title for page
dip_float	xcm	X-size of image on page, in cm.
dip_float	ycm	Y-size of image on page, in cm.
dip_int	border	Thickness of border, zero is no
		border

# ImageWriteTIFF

Write TIFF image to file (in dipIO)

#### **SYNOPSIS**

```
#include "dipio_tiff.h"
dip_Error ImageWriteTIFF ( image, filename, photometric, physDims, compression )
```

#### **FUNCTION**

This function writes the image to a TIFF file, overwriting any other file with the same name. photometric can set to let the function know how to write the TIFF image (supported colour spaces are RGB, CIE Lab and CMYK).

If photometric is not DIPIO\_PHM\_GRAYVALUE, a 3D image is expected, in which the different planes are stored along the 3rd dimension.

physDims gives physical dimensions of the image, which will be used to set the dots per inch property of the TIFF file. It can be set to 0 for default values (300 dpi). If the physDims->dimensionUnits is not given, meters are assumed.

#### **ARGUMENTS**

Data type	Name	Description

# Imaginary

Arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Imaginary ( in, out )
```

#### DATA TYPES

binary, integer, float, complex

### **FUNCTION**

Computes the imaginary part of the input image values, and outputs a float typed image.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
${\tt dip\_Image}$	out	Output

#### **SEE ALSO**

Modulus, Phase, Real

#### IncoherentOTF

Generates an incoherent OTF

#### **SYNOPSIS**

```
#include "dip_microscopy.h"
dip_Error dip_IncoherentOTF ( out, defocus, xNyquist, amplitude, otf )
```

#### DATA TYPES

Output: sfloat

#### **FUNCTION**

This function implements the formulae for a (defocused) incoherent OTF as described by Castleman. When defocus is unequal to zero, either the Stokseth approximation or the Hopkins approximation is used. The defocus is defined a the maximum defocus path length error divided by the wave length (See Castleman for details). The summation over the Bessel functions in the Hopkins formluation, is stopped when the change is smaller than DIP\_MICROSCOPY\_HOPKINS\_OTF\_CUTOFF.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	out	Output
dip_float	defocus	Defocus
dip_float	xNyquist	Oversampling
dip_float	amplitude	Amplitude
dipf_IncoherentOTF	otf	Otf approximation

The dipf\_IncoherentOTF enumeration supports the following flags:

Name	Description
DIP_MICROSCOPY_OTF_STOKSETH	Stokseth OTF approximation
DIP_MICROSCOPY_OTF_HOPKINS	Hopkins OTF approximation

#### **LITERATURE**

K.R. Castleman, "Digital image processing, second edition", Prentice Hall, Englewood Cliffs, 1996.

SEE ALSO

 ${\tt IncoherentPSF}$ 

## IncoherentPSF

Generates an incoherent PSF

#### **SYNOPSIS**

```
#include "dip_microscopy.h"
dip_Error dip_IncoherentPSF ( output, xNyquist, amplitude )
```

#### DATA TYPES

Output: sfloat

#### **FUNCTION**

This function generates an incoherent in-focus point spread function of a diffraction limited objective.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	output	Output Image
dip_float	xNyquist	Oversampling Factor
dip_float	amplitude	Amplitude

#### **LITERATURE**

K.R. Castleman, "Digital image processing, second edition", Prentice Hall, Englewood Cliffs, 1996.

## IndexToCoordinate

Convert pixel index to coordinate

#### **SYNOPSIS**

```
#include "dip_coordsindx.h"
dip_Error dip_IndexToCoordinate ( index, coordinate, stride )
```

#### **FUNCTION**

This function is identical to IndexToCoordinateWithSingletons, but does not handle images with singleton dimensions (dimensions where the size is 1). Please use the other function instead, this one is provided for backwards compatability only.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{ ext{-}}\mathtt{int}$	index	lineair index
dip_IntegerArray	coordinate	output coordinates
$\mathtt{dip}_{\mathtt{-}}\mathtt{IntegerArray}$	stride	stride array

#### **SEE ALSO**

 ${\tt IndexToCoordinateWithSingletons, CoordinateToIndex}$ 

## IndexToCoordinateWithSingletons

Convert pixel index to coordinate

#### **SYNOPSIS**

```
#include "dip_coordsindx.h"
dip_Error dip_IndexToCoordinateWithSingletons ( index, coordinate, size, stride )
```

#### **FUNCTION**

This function converts an pixel index of an image to a coordinate array. The conversion is done by calculating the modulus of the index with the stride and size arrays obtained from the image. coordinate has to be an allocated integer array with its size equal to the size of stride and size.

A set of macros can be used instead of this function to avoid some overhead when repeatedly converting linear indices to coordinates for the same image:

DIPXJ( dip\_IntegerArrayNew( &coordinates, stride->size, 0, rg ));

/\* Now, every time you need to obtain the coordinates for an index, do: \*/

```
DIP_FNR_DECLARE; /* Declares dip_Registry rg */
dip_Image image;
dip_int index;
dip_IntegerArray coordinates;
dip_IntegerArray size;
dip_IntegerArray stride;

DIP_INDEX_TO_COORDINATE_DECL( ix ); /* This macro declares variable "ix", name it whatever
DIP_FNR_INITIALISE;
/* ... */

DIPXJ( dip_ImageGetDimensions( image, &size, rg ));
DIPXJ( dip_ImageGetStride( image, &stride, rg ));

DIP_INDEX_TO_COORDINATE_INIT( size, stride, ix, rg ); /* This macro initialises variable '
```

DIP\_INDEX\_TO\_COORDINATE( index, coordinates, stride, ix );

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{int}$	index	lineair index
dip_IntegerArray	coordinate	output coordinates
dip_IntegerArray	size	image size array
dip_IntegerArray	stride	stride array

## **SEE ALSO**

IndexToCoordinate, CoordinateToIndex

## Initialise

Initialise DIPlib

## **SYNOPSIS**

```
dip_Error dip_Initialise( void )
dip_Error dipio_Initialise( void )
```

## **FUNCTION**

Initialise the DIPlib library. Must be called before using any of the other DIPlib functions. This function can be invoked more than once; all but the first invocation are ignored.

## **SEE ALSO**

Exit

## InsertionSort

Sort a block of data

## **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_InsertionSort ( data, size, dataType )
```

## **FUNCTION**

Sorts a block of data (of size  $\tt size$  and data type  $\tt dataType$  ) using the insertion sort algorithm.

## **ARGUMENTS**

Data type	Name	Description	
void *	data	Data	
dip_int	size	Size	
dip_DataType	dataType	Data type. See DIPlib's data types	

## **SEE ALSO**

# IntegerArrayCopy

Copy an array

403

## **SYNOPSIS**

dip\_Error dip\_IntegerArrayCopy ( dest, src, resources )

## **FUNCTION**

This function copies the integer array **src** to **dest**. The array **dest** is created by this function as well.

## **ARGUMENTS**

Data type	Name	Description
dip_IntegerArray *	dest	Destination array
dip_IntegerArray	src	Source array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## SEE ALSO

IntegerArrayNew, IntegerArrayFree, IntegerArrayCopy, IntegerArrayFind IntegerArrayCopy, FloatArrayCopy, ComplexArrayCopy, DataTypeArrayCopy, BooleanArrayCopy, VoidPointerArrayCopy, StringArrayCopy

# IntegerArrayFind

Find value in array

## **SYNOPSIS**

dip\_Error dip\_IntegerArrayFind ( array, value, index, found )

## **FUNCTION**

Finds a value in an array and "returns" its index in the array. If found is zero, IntegerArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP\_FALSE if value is not found).

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{ extsf{-}}\mathtt{IntegerArray}$	array	Array to find value in
dip_int	value	Value to find
dip_int *	index	Index of the found value
dip_Boolean *	found	Value found or not

## **SEE ALSO**

BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

# IntegerArrayNew

Array allocation function

#### **SYNOPSIS**

dip\_Error dip\_IntegerArrayNew ( array, size, value, resources )

## **FUNCTION**

This function allocates the size elements of a dip\_IntegerArray and sets the size of the array to size. Each array element is initialized with value.

## **ARGUMENTS**

Data type	Name	Description
dip_IntegerArray *	array	Array
dip_int	size	Size
dip_int	value	Initial value
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

IntegerArrayNew, IntegerArrayFree, IntegerArrayCopy, IntegerArrayFind
ArrayNew, IntegerArrayNew, FloatArrayNew, ComplexArrayNew, BoundaryArrayNew,
FrameWorkProcessArrayNew, DataTypeArrayNew, ImageArrayNew, BooleanArrayNew,
VoidPointerArrayNew, StringArrayNew, CoordinateArrayNew

## Invert

logic operation

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Invert ( in, out )
```

## DATA TYPES

binary, integer

## **FUNCTION**

The function Invert inverts the pixel value in in1 and stores the result in out.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Binary input image
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output image

## **SEE ALSO**

And, Xor, Or

## IsodataThreshold

Point operation

## **SYNOPSIS**

```
#include "dip_analysis.h"
dip_Error dip_IsodataThreshold ( in, out, mask, numbthresholds, values )
```

## DATA TYPES

integer, float

## **FUNCTION**

Thresholds in with the isodata method. Several threholds can be supplied, their value is returned in values. The different regions are label in out with different grey-values. A maks image mask can be given to compute the isodata only there.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask image
dip_int	numbthresholds	Number of Thresholds
dip_FloatArray	values	Values

## **SEE ALSO**

Threshold, RangeThreshold, HysteresisThreshold

## IsScalar

409

Determines whether an image is a scalar

## **SYNOPSIS**

dip\_Error dip\_IsScalar( image, answer )

## **FUNCTION**

Determines whether an image is of the DIP\_IMTP\_SCALAR type. If answer is not zero, the verdict is passed in this variable. Otherwise, dip\_IsScalar returns an error in case image fails to be a scalar.

## **ARGUMENTS**

Data type	Name	Description	
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	image	The image under investigation	
dip_Boolean *	answer	The verdict	

## Kuwahara

Edge perserving smoothing filter

#### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_Kuwahara ( in, out, se, boundary, filterSize, shape )
```

#### DATA TYPES

binary, integer, float

## **FUNCTION**

This function implements the kuwahara edge-preserving smoothing function. See section 9.4, "Smoothing operations", in Fundamentals of Image Processing for a description of the algorithm. However, this function does not implement the classical kuwahara filter, which only compares the variance of four regions in the filter window, but compares the variance of every region specified by the filter shape and size centered withing the filter window.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterSize	Filter sizes
dip_FilterShape	shape	Filter shape

The enumerator dip\_FilterShape contains the following constants:

411

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

## NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

## SEE ALSO

GeneralisedKuwahara, VarianceFilter

## Label

Label a binary image

#### **SYNOPSIS**

```
#include "dip_regions.h"
dip_Error dip_Label ( in, out, connectivity, flags, minsize, maxsize, nol, boundary )
```

#### DATA TYPES

#### binary

#### **FUNCTION**

The output is an integer image. Each object (respecting the connectivity, see The connectivity parameter) in the input image receives a unique number. This number ranges from 1 to the number of objects in the image. The pixels in the output image corresponding to a given object are set to this number (label). The remaining pixels in the output image are set to 0. The minsize and maxsize set limits on the size of the objects, if the flag DIP\_LB\_THRESHOLD\_ON\_SIZE is set: Objects smaller than minsize or larger than maxsize do not receive a label and the corresponding pixels in the output image are set to zero. Setting minsize to zero implies that there is no check with respect to the minimum size of the object, and the same holds for maxsize and the maximum size of the object. If the flag DIP\_LB\_LABEL\_IS\_SIZE is set, the objects' labels are set to the objects' sizes. The boundary conditions are generally ignored (labeling stops at the boundary). The exception is DIP\_BC\_PERIODIC, which is the only one that makes sense for this algorithm.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input binary image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output label image
dip_int	connectivity	Connectivity
dip_int	flags	0, or a logical OR of the flags described above
dip_int	minsize	Minimum size of the objects (0=do not check)
dip_int	maxsize	Maximum size of the objects (0=do not check)
dip_int *	nol	Pointer to dip_int. Used for returning the number
		of objects. May be set to 0.
dip_BoundaryArray	boundary	Boundary conditions

# Laplace

Second order derivative filter

## **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_Laplace ( in, out, boundary, ps, sigmas, tc, flavour )
```

## DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float** 

## **FUNCTION**

Computes the Laplace of an image using the Derivative function.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	ps	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_float	tc	Truncation of Gaussian
dip_DerivativeFlavour	flavour	Derivative flavour

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

## **SEE ALSO**

See section 9.5, "Derivative-based operations", in Fundamentals of Image Processing.

 ${\tt Derivative, GradientMagnitude, GradientDirection2D, Dgg, LaplacePlusDgg, LaplaceMinDgg}$ 

# LaplaceMinDgg

Second order derivative filter

#### **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_LaplaceMinDgg ( in, out, boundary, ps, sigmas, tc, flavour )
```

## DATA TYPES

Depends on the underlying implementation, but expect:

binary, integer,  ${\bf float}$ 

#### **FUNCTION**

Computes Laplace - Dgg. For two-dimensional images this is equivalent to the second order derivative in the direction perpendicular to the gradient direction.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}Image$	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	ps	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_float	tc	Truncation of Gaussian
dip_DerivativeFlavour	flavour	Derivative flavour

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

## **SEE ALSO**

Derivative, GradientMagnitude, GradientDirection2D, Laplace, Dgg, LaplacePlusDgg

# LaplacePlusDgg

Second order derivative filter

## **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_LaplacePlusDgg ( in, out, boundary, ps, sigmas, tc, flavour )
```

#### DATA TYPES

Depends on the underlying implementation, but expect: binary, integer, **float** 

#### **FUNCTION**

Computes the laplace and the second derivative in gradient direction of an image using the <code>Derivative</code> function and adds the results. The zero-crossings of the result correspond to the edges in the image, just as for the individual Laplace and Dgg operators. The localization is improved by an order of magnitude with respect to the individual operators.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	ps	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_float	tc	Truncation of Gaussian
dip_DerivativeFlavour	flavour	Derivative flavour

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

Lee

Morphological edge detector

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_Lee ( in, out, se, boundary, filterParam, shape, edgeType,
flags )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Implements a morphological edge detector based on the minimum of two complementary morphological operations. These can be chosen through the edgeType parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape
dip_MphEdgeType	edgeType	Edge type
dipf_LeeSign	flags	Lee sign flag

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The enumerator  ${\tt dip\_MphEdgeType}$  contains the following constants:

Name	Description
DIP_MPH_TEXTURE	Response is limited to edges in texture
DIP_MPH_OBJECT	Response is limited to object edges
DIP_MPH_BOTH	All edges produce equal response

The enumerator dipf\_LeeSign contains the following constants:

Name	Description
DIP_LEE_UNSIGNED	Absolute edge strength
DIP_LEE_SIGNED	Signed edge strength

## **SEE ALSO**

 ${\tt MorphologicalGradientMagnitude,\,MorphologicalRange,\,\,} \\ {\tt MultiScaleMorphologicalGradient,\,Tophat}$ 

## Lesser

Compare grey values in two images

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Lesser ( in1, in2, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function sets each pixel in out to "true" when for corresponding pixels in1 < in2. This is the same as Compare with the DIP\_SELECT\_LESSER selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

## **ARGUMENTS**

Data type	Name	Description	
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in1	First input	
dip_Image	in2	Second input	
dip_Image	out	Output	

## **SEE ALSO**

 ${\tt Compare, Threshold, Equal, Greater, NotEqual, NotGreater, NotLesser, SelectValue, NotZero}$ 

Ln

421

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Ln ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the natural logarithm of the input image values.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

Sqrt, Exp, Exp2, Exp10, Log2, Log10

## LnGamma

## mathematical function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_LnGamma ( in, out )
```

## DATA TYPES

binary, integer, **float** 

## **FUNCTION**

Computes the natural logarithm of the gamma function of the input image values.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

BesselJO, BesselJI, BesselJN, BesselYO, BesselYI, BesselYN, Erf, Erfc, Sinc

## LnNormError

difference measure

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_LnNormError ( in1, in2, mask, out, order )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Calculates the order norm difference between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

## **ARGUMENTS**

Data type	Name	Description	
dip_Image	in1	First input	
dip_Image	in2	Second input	
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask	
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	out	Output	
dip_float	order	Order	

## **SEE ALSO**

MeanError, MeanSquareError, RootMeanSquareError, MeanAbsoluteError, IDivergence

## LocalMinima

Marks local minima (or regional minima)

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_LocalMinima ( in, mask, out, connectivity, max_depth, max_size, binaryOutput )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

The binary output image is true on all pixels belonging to the minima of a region (as defined by the watershed). To find local maxima, use the inverse of the image as input to this function (see Invert). If binaryOutput is DIP\_FALSE, the output is a labelled image instead of a binary one. In this case, pixels belonging to the same local minimum are assigned the same value.

The algorithm is based on the watershed transform, see Watershed for information on the parameters.

Minima is a different algorithm to obtain local minima; Maxima yields the local maxima.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	mask	Mask
dip_Image	out	Output (binary)
dip_int	connectivity	Connectivity
dip_float	max_depth	Maximum depth of a region that can be merged
dip_int	max_size	Maximum size of a region that can be merged
dip_Boolean	binaryOutput	DIP_FALSE if the output should be a labelled image

## **SEE ALSO**

 ${\tt Watershed}, {\tt SeededWatershed}, {\tt UpperEnvelope}, {\tt Minima}, {\tt Maxima}$ 

# Log10

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Log10 ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the base ten logarithm of the input image values.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

Sqrt, Exp, Exp2, Exp10, Ln, Log2

Log2

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Log2 ( in, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Computes the base two logarithm of the input image values.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

Sqrt, Exp, Exp2, Exp10, Ln, Log10

## macros.h

Various macros

#### **DESCRIPTION**

The include files dip\_macros.h contains a number of useful macros.

#### Math macros

DIP_ABS( x )	Absolute value of x
DIP_MAX(x, y)	Maximum of x and y
DIP_MIN(x, y)	Minimum of x and y
DIP_FUNC( funcName, suffix )	Attaches the suffix to the function name,
	and puts and underscore in between.
DIP_SWAP(x, y, z)	Swaps variables x and y, using temporary
	variable z. Must be followed by a trailing
	" <del>,</del> "

#### Macros for handling complex numbers:

DIP_REAL( x )	Real part of complex number x
DIP_IMAGINARY( x )	Imaginary part of complex number x
DIP_SQUARE_MODULUS( x )	Square modulus of complex number x
DIP_MODULUS( x )	Modulus of complex number x
DIP_PHASE( x )	Phase of complex number x

## Binary I/O macros

<pre>DIP_BINARY_MASK( mask, plane )</pre>	Computes a binary mask from the plane
	value
DIP_BINARY_READ( in, mask )	Returns the binary value from in
DIP_BINARY_WRITE( out, val, mask )	Writes the value of val to out

Random access I/O macros:

```
DIP_PIXEL_GET( ip, pos, stride, value )
DIP_PIXEL_SET( ip, pos, stride, value )
```

get/set the value of the pixel at position pos from data pointer ip with strides stride. Both pos and stride are dip\_IntegerArrays.

```
DIP_PIXEL_ADD( ip, pos, stride, value )
DIP_PIXEL_SUB( ip, pos, stride, value )
DIP_PIXEL_MUL( ip, pos, stride, value )
DIP_PIXEL_DIV( ip, pos, stride, value )
```

add/subtract/multlipy/divide the value with the pixel-value at position pos from data pointer ip with strides stride. Both pos and stride are dip\_IntegerArrays.

Map

Remaps an image

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_Map ( in, out, map, mirror )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

This function maps the dimensions of the output image to (different) dimensions of the input image. The array index of map specifies the dimension of the output image, the value of the array element of map specifies to which dimension in the input image it corresponds. Optionally, the dimensions can be mirrored, when the value of the corrsponding array element in mirror is set to DIP\_TRUE.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image
dip_IntegerArray	map	Map array
dip_BooleanArray	mirror	Mirror array

## **SEE ALSO**

Mirror

Max

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Max ( in1, in2, out )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function computes out = max (in1, in2) on a pixel by pixel basis. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

## **ARGUMENTS**

Data type	Name	Description	
${\tt dip\_Image}$	in1	First input	
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input	
dip_Image	out	Output	

## **SEE ALSO**

MaxFloat, Min, MinFloat

## MaxFloat

arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_MaxFloat ( in, out, constant )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function computes out = max(in, constant) on a pixel by pixel basis. The data types of the in1 image and constant may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
dip_float	constant	Constant

## **SEE ALSO**

Max, Min, MinFloat

## Maxima

Detects local maxima

#### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_Maxima ( in, mask, out, connectivity, booleanOutput )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

This function detects local maxima.

The algorithm finds a connected set of pixels with identical value, an no neighbours with higher value. This set is a local maximum and its pixels are set to 1 in the output image. If booleanOutput is false, the output image is a labelled image.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input image
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	mask	Mask image
dip_Image	out	Binary output image
dip_int	connectivity	Connectivity
dip_Boolean	booleanOutput	Give a binary output image?

#### NOTE

If you are looking for the old version of Maxima, it is still available through the following combination of commands:

```
dip_Dilation( in, out, se, boundary, filterParam, shape );
dip_Equal( in, out, out );
```

## **SEE ALSO**

Minima, LocalMinima, SeededWatershed, GrowRegions

## Maximum

statistics function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Maximum ( in, mask, out, ps )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

Calculates the maximum of the pixel values over all those dimensions which are specified by ps.

## **ARGUMENTS**

Data type	Name	Description

Mean

439

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Mean ( in, mask, out, ps )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

Calculates the mean of the pixel values over all those dimensions which are specified by ps.

# **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_Image	mask (0)	Mask
dip_Image	out	Output
dip_BooleanArray	ps (0)	Dimensions to project

## **SEE ALSO**

From images to scalars

Sum, Variance, StandardDeviation, MeanModulus, SumModulus, MeanSquareModulus, Maximum, Minimum, Median, Percentile

## MeanAbsoluteError

difference measure

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_MeanAbsoluteError ( in1, in2, mask, out )
```

#### DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Calculates the mean absolute error difference between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

#### **ARGUMENTS**

Data type	Name	Description	
dip_Image	in1	First input	
dip_Image	in2	Second input	
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask	
dip_Image	out	Output

#### Measure

Measure object features

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_Measure ( measurement, featureID, featureParams, objectID,
objectIm, intensityIm, connectivity, physDims )
```

#### DATA TYPES

objectIm: integer

intensityIm: integer, float

#### **FUNCTION**

The Measure function is the top-level function of DIPlib's measurement library. This function performs measurements of the objects in the specified objectIm image. The measurements to be performed are specified by the featureID array of measurement function IDs. If featureParams is non-zero, its size should equal that of featureID. Although the current implementation of Measure does not make use of this argument, future versions will pass the data pointers of the featureParams to the corresponding measurement functions. featureParams should be set to zero for now.

The list of object IDs on which the measurements have to be performed is specified by objectID. If it is zero, Measure will call GetObjectLabels to obtain a list of all non-zero values in objectIm. The objectID values should be unequal to zero.

The state of measurement should be raw (see MeasurementNew), since Measure will forge the measurement data structure by calling MeasurementForge.

The intensityIm image defines the pixel intensity of the objects, whose shape is defined by objectIm. If none of the measurements specified in featureID require the grey-value image, it can be set to NULL.

The physDims parameter defines the physical dimensions of the pixel sizes and pixel intensity. See PhysicalDimensionsNew for more information.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_IntegerArray	featureID	Array of measurement function IDs
$ ext{dipVoidPointerArray}$	featureParams (0)	Set to zero
dip_IntegerArray	objectID (0)	Array of Object IDs
dip_Image	objectIm	Image containing object IDs, i.e.
		object labels
${\tt dip\_Image}$	intensityIm	Intensity image
dip_int	connectivity	Connectivity of object's contour
		pixels, see The connectivity
		parameter
dip_PhysicalDimensions	physDims	Structure specifying the physical
		dimensions of the image pixels

# MeasurementFeatureConvert

Convert the data of a measurement feature

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureConvert ( in, featureID, inID, out, outID,
resources )
```

#### **FUNCTION**

This function convert the data of object inID in measurement in measured by feature featureID to object outID in out.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	in	Input measurement data structure
dip_int	featureID	ID of the measurement feature
dip_int	inID	ID of the object in in
dip_Measurement	out	Output measurement data structure
dip_int	outID	ID of the object in out
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

Measure, MeasurementNew

# MeasurementFeatureDescription

Measurement Description access function

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureDescription ( measurement, featureID,
description, resources )
```

#### **FUNCTION**

The MeasurementObjectData, MeasurementObjectValue and MeasurementFeatureDescription functions provide access to the functions that are registered by each measurement function. See also MeasurementFeatureRegister.

This function gives access to a structure containing the name, a short description of the measurement feature, as well as the labels and units of the data measured by the feature specified with featureID. Use the functions FeatureDescriptionGetName, FeatureDescriptionGetDescription, FeatureDescriptionGetLabels and FeatureDescriptionGetUnits to access the values in the description structure.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement feature ID
dip_FeatureDescription *	description	Pointer to a dip_FeatureDescription
		structure containing a description of the
		specified feature
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

#### **SEE ALSO**

# MeasurementFeatureFormat

Feature data format convenience function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureFormat ( measurement, featureID, format )
```

#### **FUNCTION**

This function is a convenience function on top of MeasurementObjectValue, providing an easy access to the data format of the measurement values of the featureID measurement function.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
dipf_MeasurementValueFormat *	format	Pointer to measurement value data
		format

## **SEE ALSO**

MeasurementObjectValue, MeasurementNew

# MeasurementFeatureRegister

Register a measurement function

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegister ( registry )
```

#### **FUNCTION**

This function registers a measurement function, specified by registry. Once a function is registered, it can be used through the Measure function by specifying registry.id.rtid as the measurement ID. registry contains pointers to a series of functions related to making the measurement, and contains information on how these functions should be called. See below for more information.

#### **ARGUMENTS**

Data type	Name	Description
dip_MeasurementFeatureRegistry	registry	Registry

#### THE REGISTRY STRUCTURE

The dip\_MeasurementFeatureRegistry structure contains the following fields:

Data type	Name	Description
dip_Identifier	id	Unique identifier
dipf_FeatureMeasureFunction	type	Type of function measure
		points to
$ ext{dip\_FeatureCreateFunction}$	create	Function pointer, see
		FeatureCreateFunction
dip_FeatureComposeFunction	compose	Function pointer, see
		FeatureComposeFunction
dip_FeatureMeasureFunction	measure	Union of function pointers
dip_FeatureValueFunction	value	Function pointer, see
		FeatureValueFunction
dip_FeatureDescriptionFunction	description	Function pointer, see
		FeatureDescriptionFunction
dip_FeatureConvertFunction	convert	Function pointer, see
		FeatureConvertFunction
dip_int	iterations	Currently ignored (set to 1)
dip_Boolean	needIntensityIm	Whether or not a grey-value
		image is needed

dip\_Identifier is a struct with two values: uuid and rtid. rtid is of type dip\_int, and needs to be set to a unique number (use GetUniqueNumber for that). uuid is curently ignored, but should be set to a universally unique number by using the time, date and processor ID at the time of writing the code.

measure points to the main measuring function, and can be of four different types, based on how it does the measuring. measure is a union with the following fields:

Data type	Name	Description
dip_FeatureLineFunction	line	Takes one image line at the time, see
		FeatureLineFunction
dip_FeatureImageFunction	image	Takes the whole image at once, see
		FeatureImageFunction
dip_FeatureChainCodeFunction	chaincode	Takes one chain code at the time, see
		FeatureChainCodeFunction
dip_FeatureCompositeFunction	composite	Combines the results of various other
		measurements, see
		FeatureCompositeFunction

The type flag should match the function type pointed to, and can be one of the following:

Name	Description
DIP_MSR_FUNCTION_LINE_BASED	measure.line is set
DIP_MSR_FUNCTION_IMAGE_BASED	measure.image is set
DIP_MSR_FUNCTION_CHAINCODE_BASED	measure.chaincode is set
DIP_MSR_FUNCTION_COMPOSITE	measure.composite is set

create points to a function that initialises any data before the measurement can start.
value points to a function that returns the measurement result (called by
MeasurementObjectValue). description points to a function that returns information on
the measurement performed (called by MeasurementFeatureDescription). convert points

to a function that copies the collected measurement data to a second measurement object (called MeasurementFeatureConvert). Finally, the compose element points to a function that returns the list of measurement IDs that the DIP\_MSR\_FUNCTION\_COMPOSITE function depends on. This value is ignored for other types of measurement functions.

needIntensityIm should be set if the measurement function expects a grey-value input as well as the labeled image.

# MeasurementFeatureRegistryFeatureDescription

Get the feature description of a registered measurement feature

#### **SYNOPSIS**

#include "dip\_measurement.h"
dip\_Error dip\_MeasurementFeatureRegistryFeatureDescription ( featureID,
description, resources )

#### **FUNCTION**

This function obtains the feature description information of the measurement feature specified by featureID.

#### **ARGUMENTS**

Data type	Name	Description
dip_int	featureID	Measurement feature ID
dip_FeatureDescription *	description	pointer to a dip_FeatureDescription
		structure containing descriptive
		information of the measurement feature.
		This data can be accessed with
		MsrDescriptionFunction
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

#### SEE ALSO

 $\label{lem:measurementFeatureRegistryFeatureNeedsIntensityImage, MeasurementFeatureValid, \\ MeasurementFeatureDescription, \\ MeasurementObjectData, \\ MeasurementObjectValue \\ \\$ 

# ${\tt MeasurementFeatureRegistryFeatureNeedsIntensityImage}$

Checks whether the measurement function needs an intensity image

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegistryFeatureNeedsIntensityImage (
featureID, veredict )
```

#### **FUNCTION**

This function sets veredict to DIP\_TRUE if the measurement feature specified by featureID requires a grey-value image, or DIP\_FALSE otherwise.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{int}$	featureID	Measurement feature ID
dip_Boolean *	veredict	Return value

#### SEE ALSO

Measure, MeasurementFeatureRegister, MeasurementFeatureRegistryList, MeasurementFeatureRegistryGet, MeasurementFeatureRegistryFeatureDescription, MeasurementFeatureValid, MeasurementFeatureDescription, MeasurementObjectData, MeasurementObjectValue

# MeasurementFeatureRegistryGet

Get the registry information of a measurement feature

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegistryGet ( featureID, registry )
```

#### **FUNCTION**

This function obtains (a copy of) the registry structure of the measurement feature function specified by featureID.

#### **ARGUMENTS**

Data type	Name	Description
dip_int	featureID	Measurement function ID
dip_MeasurementFeatureRegistry *	registry	Pointer to a measurement feature
		registry structure

#### SEE ALSO

Measure, MeasurementFeatureRegister, MeasurementFeatureRegistryList,
MeasurementFeatureRegistryFeatureDescription,
MeasurementFeatureRegistryFeatureNeedsIntensityImage, MeasurementFeatureValid,
MeasurementFeatureDescription, MeasurementObjectData, MeasurementObjectValue

# ${\tt MeasurementFeatureRegistryList}$

Obtain a list of the registered measurement features

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureRegistryList ( featureID, resources )
```

#### **FUNCTION**

This functions obtains an array of registered measurement feature IDs.

#### **ARGUMENTS**

Data type	Name	Description
dip_IntegerArray *	featureID	Pointer to an array of measurement feature IDs
dip_Resources	resources	Resources tracking structure. See ResourcesNew

#### **SEE ALSO**

Measure, MeasurementFeatureRegister, MeasurementFeatureRegistryGet,
MeasurementFeatureRegistryFeatureDescription,
MeasurementFeatureRegistryFeatureNeedsIntensityImage, MeasurementFeatureValid,
MeasurementFeatureDescription, MeasurementObjectData, MeasurementObjectValue

# MeasurementFeatures

Get the measurement ID array

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatures ( measurement, featureID, resources )
```

#### **FUNCTION**

This function obtains an array of measurement function IDs in the measurement structure. See MeasurementForge for a (brief) explination of the measurement data structure.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_IntegerArray *	featureID	pointer to an array of measurement function IDs
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# MeasurementFeatureSize

Feature data convenience function

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureSize ( measurement, featureID, size )
```

#### **FUNCTION**

This function is a convenience function on top of MeasurementObjectValue, providing an easy access to the number of the measurement values of the featureID measurement function.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	ID of the measurement feature
dip_int *	size	Number of measurement values

## **SEE ALSO**

MeasurementObjectValue, MeasurementNew

# MeasurementFeatureValid

Verify a measurement feature ID

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFeatureValid ( measurement, featureID, verdict )
```

#### **FUNCTION**

This function determines whether featureID is a valid measurement feature, by verifying whether featureID equals the ID of one of the registered measurement features. If verdict is not zero, the result (DIP\_TRUE or DIP\_FALSE) is stored in verdict, otherwise an error is returned in case the verification fails.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement feature ID to validated
dip_Boolean *	verdict	Pointer to the boolean verdict

#### **SEE ALSO**

Measure, MeasurementNew, MeasurementFeatures, MeasurementFeatureDescription, MeasurementFeatureRegister, MeasurementFeatureRegistryList, MeasurementFeatureRegistryGet, MeasurementFeatureRegistryFeatureDescription, MeasurementFeatureRegistryFeatureNeedsIntensityImage

# MeasurementForge

461

Allocate the data of a measurement data structure

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementForge ( measurement, featureID, objectID )
```

#### **FUNCTION**

This function forges a measurement data structure, that has been created with MeasurementNew. The featureID array should contain the IDs of the features to be performed. The vadility of these IDs is checked by comparing them with the IDs of registered measurement functions (see MeasurementFeatureRegister). The objectID array contains the IDs (i.e. labels) of the objects on which the features are to be performed. (For example, the Measure function accepts as one of its arguments a label image, of which the intensity of each individual pixel represents the ID of the object to which that pixel belongs. These label values should in that case correspond to the values of objectID.)

The measurement structure can be regarded as a matrix spanned by the number of features along one axis, and the number of objects along the other. MeasurementForge allocates and initialises the internal structures to contain this matrix and the data required for each conbimation of measurement and object ID.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement structure
dip_IntegerArray	featureID	Array of measurement function IDs
dip_IntegerArray	objectID	Array of Object IDs

#### **SEE ALSO**

Measure, MeasurementNew, MeasurementFree, MeasurementIsValid,
MeasurementFeatureRegister, MeasurementFeatureRegistryList,
MeasurementFeatureRegistryGet, MeasurementFeatureRegistryFeatureDescription,
MeasurementFeatureRegistryFeatureNeedsIntensityImage

# MeasurementFree

Free a measurement data structure

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementFree ( measurement )
```

#### **FUNCTION**

This function frees a Measurement data structure. After the Measurement has been freed, the pointer measurement is set to zero.

## **ARGUMENTS**

Data type	Name	Description
dip_Measurement *	measurement	pointer to the measurement structure to be freed

## **SEE ALSO**

 ${\tt Measure}, \, {\tt MeasurementNew}, \, {\tt MeasurementForge}, \, {\tt MeasurementIsValid}$ 

# MeasurementGetName

Get the name of a Measurement structure

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementGetName ( measurement, name, resources )
```

#### **FUNCTION**

This function gets the name of a measurement structure

## **ARGUMENTS**

Data type	Name	Description	
dip_Measurement	measurement	Measurement	
dip_String *	name	Name	
dip_Resources	resources	Resources tracking structure. See ResourcesNew	

## **SEE ALSO**

Measure, MeasurementNew, MeasurementID, MeasurementSetName, MeasurementGetPhysicalDimensions, MeasurementSetPhysicalDimensions

# ${\tt MeasurementGetPhysicalDimensions}$

Get the physical dimensions info of a measurement

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementGetPhysicalDimensions ( measurement, physDims,
resources )
```

#### **FUNCTION**

This function obtains a copy of the physical dimensions information associated with the measurement data structure. The physical dimensions data structure informs measurement features about the physical sizes and position of the pixels of the measured image.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_PhysicalDimensions *	physDims	Pointer to a Physical Dimensions data
		structure
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

## **SEE ALSO**

# MeasurementID

465

Get the ID of a Measurement structure

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementID ( measurement, id )
```

#### **FUNCTION**

This function obtains the ID of a the measurement structure. The ID is a DIPlib wide unique number (see GetUniqueNumber).

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement structure
dip_int *	id	Pointer to the id

## **SEE ALSO**

Measure, MeasurementNew, MeasurementSetName, MeasurementGetName, MeasurementGetPhysicalDimensions, MeasurementSetPhysicalDimensions

## MeasurementIsValid

Checks whether a measurement is valid

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementIsValid ( measurement, verdict )
```

#### **FUNCTION**

This function determines whether measurement is forged. If verdict is not zero, the result (DIP\_TRUE or DIP\_FALSE) is stored in verdict, otherwise an error is returned in case the verification fails.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_Boolean *	verdict	The validation verdict

#### **SEE ALSO**

 ${\tt Measure}, \, {\tt MeasurementNew}, \, {\tt MeasurementFree}, \, {\tt MeasurementForge}$ 

## MeasurementNew

Create new measurement data structure

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementNew ( measurement, resources )
```

#### **FUNCTION**

This function creates, by allocating and initialising it, a new Measurement data structure. After this function has been used to create a new measurement structure, the state of it is raw. It needs to be passed through MeasurementForge before it can be used to store measurement results.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement *	measurement	pointer to the measurement structure to be created
dip_Resources	resources	Resources tracking structure. See ResourcesNew

#### SEE ALSO

MeasurementFree, MeasurementForge, MeasurementIsValid, MeasurementID, MeasurementSetName, MeasurementGetName, MeasurementGetPhysicalDimensions, MeasurementSetPhysicalDimensions, MeasurementNumberOfFeatures, MeasurementFeaturevalid, MeasurementFeatureDescription, MeasurementNumberOfObjects, MeasurementObjects, MeasurementObjectValid, MeasurementObjectData, MeasurementObjectValue, MeasurementFeatureConvert, MeasurementWrite

# MeasurementNumberOfFeatures

Get the number of measurement feature IDs

## **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementNumberOfFeatures ( measurement, features )
```

#### **FUNCTION**

This function obtains the number of measurement feature IDs in the measurement structure. See MeasurementForge for a (brief) explination of the measurement data structure.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int *	features	pointer to the number of measurement feature IDs

## **SEE ALSO**

Measure, MeasurementNew, MeasurementFeatures

# MeasurementNumberOfObjects

Get the number of object IDs

### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementNumberOfObjects ( measurement, objects )
```

### **FUNCTION**

This function obtains the number of object IDs belonging to the featureID measurement function ID in the measurement structure. See MeasurementForge for a (brief) explination of the measurement data structure.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int *	objects	Pointer to an integer containing the number of object
		IDs

### SEE ALSO

Measure, MeasurementNew, MeasurementObjects

# MeasurementObjectData

Object data access function

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementObjectData ( measurement, featureID, objectID, data,
verdict )
```

### **FUNCTION**

The MeasurementObjectData, MeasurementObjectValue and MeasurementFeatureDescription functions provide access to the functions that are registered by each measurement function. See also MeasurementFeatureRegister.

The Object data is the data allocated by a measurement function for internal purposes, for example to store intermediate results. Its format is free. Therefore, the use of this function is only meaningful for a particular measurement function itself. To access the measurement values of a measurement function, use MeasurementObjectValues.

The verdict parameter provides a means to test whether featureID or objectID are valid within the context of measurement. If one of them is invalid, and verdict is not zero, \*verdict is set to DIP\_FALSE, otherwise its value is DIP\_TRUE. If verdict is zero, MeasurementObjectData produces an error when either featureID or objectID is invalid.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement data structure	
dip_int	featureID	Measurement function ID
dip_int	objectID	Object ID
void **	data	Pointer to the internal measurement data pointer
dip_Boolean *	verdict	Pointer to a boolean containing validation
		information

#### SEE ALSO

MeasurementFeatureRegistryFeatureNeedsIntensityImage

# MeasurementObjects

Get an object ID array

471

### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementObjects ( measurement, featureID, objectID,
resources )
```

### **FUNCTION**

This function obtains an array of object IDs belonging to the **featureID** measurement function in the measurement structure. See **MeasurementForge** for a (brief) explination of the measurement data structure.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
dip_IntegerArray *	objectID	Pointer to an object ID array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

### SEE ALSO

Measure, MeasurementNew, MeasurementNumberOfObjects, MeasurementObjectValid, MeasurementObjectData, MeasurementObjectValue

# MeasurementObjectValid

Verify an object ID

### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementObjectValid ( measurement, featureID, objectID,
verdict )
```

### **FUNCTION**

This function determines whether the object ID objectID, belonging to the measurement function ID featureID, is a valid object ID, by comparing objectID to the object IDs belonging to the featureID in measurement. If verdict is not zero, the result (DIP\_TRUE or DIP\_FALSE) is stored in verdict, otherwise an error is returned in case the verification fails.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
$\mathtt{dip}_{-}\mathtt{int}$	objectID	Object ID
dip_Boolean *	verdict	Pointer to a boolean containing the validation verdict

### **SEE ALSO**

 $\label{thm:measurement0bjects} \mbox{\tt Measurement0bjectbata}, \mbox{\tt Measurement0bjectValue} \\ \mbox{\tt Measurement0bjectValue}$ 

# MeasurementObjectValue

Object value access function

### **SYNOPSIS**

#include "dip\_measurement.h"
dip\_Error dip\_MeasurementObjectValue ( measurement, featureID, objectID,
data, format, resources )

### **FUNCTION**

The MeasurementObjectData, MeasurementObjectValue and MeasurementFeatureDescription functions provide access to the functions that are registered by each measurement function. See also MeasurementFeatureRegister.

The MeasurementObjectValue function provides access to the measurement values produced by the featureID measurement function measured on the objectID labeled object. The format of data is specified by format.

#### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_int	featureID	Measurement function ID
dip_int	objectID	Object ID
void **	data	Pointer to data pointer
dipf_MeasurementValueFormat *	format	Pointer to the data format label
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

#### Measurement data formats

Name	Description
DIP_MSR_VALUE_FORMAT_INTEGER	Integer scalar data format
DIP_MSR_VALUE_FORMAT_FLOAT	Float scalar data format
DIP_MSR_VALUE_FORMAT_INTEGER_ARRAY	Integer array data format
DIP_MSR_VALUE_FORMAT_FLOAT_ARRAY	Float array data format
DIP_MSR_VALUE_FORMAT_IMAGE	Data is formatted as an dip_Image

### **SEE ALSO**

Measure, MeasurementNew, MeasurementObjects, MeasurementObjectData, MeasurementObjectValue, MeasurementFeatureDescription,

MeasurementFeatureFormat, MeasurementFeatureSize, MeasurementFeatureRegister, MeasurementFeatureRegistryList, MeasurementFeatureRegistryGet, MeasurementFeatureRegistryFeatureDescription, MeasurementFeatureRegistryFeatureNeedsIntensityImage

### MeasurementRead

475

Read measurement results from a file

#### **SYNOPSIS**

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementRead ( measurement, filename, format,
addExtensions, recognised )
```

### **FUNCTION**

This function reads measurement data from a file and puts it in measurement. measurement must be allocated before calling this function. If format is 0, all different MeasurementRead functions are called in sequence until the correct format has been found. If you know the format, get the correct format ID through the registry functions.

The boolean addExtensions specifies whether MeasurementRead should try to add file format extensions to filename, if the registered file format reader fails to recognise filename straight away. The extensions are provided by the registered file readers.

If recognised is not zero, MeasurementRead will set it to DIP\_TRUE when it has been able to read filename, and it will set it to DIP\_FALSE when it is not able to read the file. No error will be generated in this case.

### NOTE

There are currently no measurement reading functions, so this function will always fail.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_String	filename	File name to read from
dip_int	format	ID of file format
dip_Boolean	addExtensions	Add extensions when looking for the file
dip_Boolean *	recognised	Set to DIP_TRUE if the file was found

### **SEE ALSO**

Measure, MeasurementWrite

# MeasurementSetName

Set the name of a measurement structure

# **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementSetName ( measurement, name )
```

### **FUNCTION**

This function sets the name of measurement to name.

# **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement
dip_String	name	Name

### **SEE ALSO**

Measure, MeasurementNew, MeasurementID, MeasurementGetName, MeasurementGetPhysicalDimensions, MeasurementSetPhysicalDimensions

# ${\tt MeasurementSetPhysicalDimensions}$

Set the physical dimensions info of the measurement

### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementSetPhysicalDimensions ( measurement, physDims )
```

### **FUNCTION**

This function sets the physical dimensions information for the measurement data structure. The physical dimensions data structure informs measurement features about the physical sizes and position of the pixels of the measured image.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_PhysicalDimensions	physDims	Physical Dimensions data structure

### **SEE ALSO**

 ${\tt Measure}, \, {\tt MeasurementNew}, \, {\tt MeasurementID}, \, {\tt MeasurementSetName}, \, {\tt MeasurementGetName}, \, {\tt MeasurementGetPhysicalDimensions}$ 

# MeasurementToHistogram

Creats a histogram for a measurement

### **SYNOPSIS**

```
#include "dip_measurement.h" #include "dip_distribution.h"
dip_Error dip_MeasurementToHistogram ( histogram, measurement, featureID, binSize, maximum, minimum, percentage, addMeasurement )
```

### DATA TYPES

### integer

### **FUNCTION**

This function creates a (possibly multi-dimensional) histogram with the measurement results of one feature. If addMeasurement is DIP\_TRUE, new data points are added to the existing histogram, and binSize, maximum, minimum and percentage input arguments are ignored. Otherwise, histogram is destroyed and recreated according to the chosen values for binSize, maximum, minimum and percentage. If percentage is DIP\_TRUE, maximum and minimum represent a percentage of the data range, otherwise they represent absolute values. If maximum or minimum are NULL, the maximum or minimum of the data is used.

### **ARGUMENTS**

Data type	Name	Description
dip_Distribution	histogram	Output histogram
dip_Measurement	measurement	Measurement data
dip_IntegerArray	featureID	List of feature IDs to use
dip_FloatArray	binSize	Size of the histogram bins
dip_FloatArray	maximum	Maximum value represented in the histogram
dip_FloatArray	minimum	Minimum value represented in the histogram
dip_Boolean	percentage	Whether maximum and minimum are percentages
dip_Boolean	addMeasurement	Whether to add data to histogram or create a
		new one

### SEE ALSO

Measure, MeasurementToImage, ObjectToMeasurement

# MeasurementToImage

Exports the data in a measurement structure to an image

### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_MeasurementToImage ( measurement, out, measurementIDs, objects
)
```

### DATA TYPES

### float

# **FUNCTION**

This function creates an image and writes the measurement data to it as if it were a table, measurements along the first dimension, objects along the second dimension.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Input measurement
dip_Image	out	Output image
dip_IntegerArray	measurementIDs	List of measurement IDs to export
dip_IntegerArray	objects	List of object IDs to export

# **SEE ALSO**

 ${\tt Measure}, {\tt ObjectToMeasurement}, {\tt MeasurementToHistogram}$ 

# MeasurementWrite

Write measurement results to a file

### **SYNOPSIS**

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementWrite ( measurement, filename, format, labels )
```

### **FUNCTION**

This function writes measurement data to a file, overwriting any other file with the same name. Get the format ID through the registry functions. If format is 0, CSV is used.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_String	filename	File name to write to
dip_int	format	ID of file format
dip_Boolean	labels	DIP_TRUE to write labels to file

### **SEE ALSO**

 ${\tt Measure}, {\tt MeasurementRead}, {\tt MeasurementWriteCSV}, {\tt MeasurementWriteHTML}, {\tt MeasurementWriteText}$ 

# MeasurementWriteCSV

Write measurement results to a CSV file

### **SYNOPSIS**

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementWriteCSV (measurement, filename, separator, labels)
```

### **FUNCTION**

This function writes the measurement results to a comma separated values (CSV) file, overwriting any other file with the same name.

This function calls MeasurementWriteText with the proper settings.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_String	filename	File name to write to
char *	separator	Characters to separate values
dip_Boolean	labels	DIP_TRUE to write labels to file

# **SEE ALSO**

 ${\tt Measure}, \, {\tt MeasurementWrite}, \, {\tt MeasurementWriteText}$ 

# MeasurementWriteHTML

Write measurement results to an HTML file

# **SYNOPSIS**

#include "dipio\_measurement.h"
dip\_Error dipio\_MeasurementWriteHTML (measurement, filename, separator, labels)

### **FUNCTION**

This function writes the measurement results to a formatted HTML file, overwriting any other file with the same name.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
dip_String	filename	File name to write to
char *	separator	Characters to separate values
dip_Boolean	labels	DIP_TRUE to write labels to file

# **SEE ALSO**

Measure, MeasurementWrite

# MeasurementWriteText

Write measurement results as readable text

#### **SYNOPSIS**

```
#include "dipio_measurement.h"
dip_Error dipio_MeasurementWriteText ( measurement, fp, options )
```

#### **FUNCTION**

This function saves/prints the results of a measurement stored in the measurement data structure. Since it will save the results to the fp FILE pointer (which has to be opened before this function is called, and closed afterwards), the results can be printed to a screen (specify stdout as fp) or to a file.

The results are saved in a matrix, with a column for each measurement, and a row for each object. The first column contains the object ID. The options structure provides a means to adjust the formatting of the measurement data. Its separator variable specifies the column separator character, the rows are separated by a newline. If the labelAlign variable is DIP\_TRUE, the separator is repeated such that the columns are aligned. If the labels variable is DIP\_TRUE, the first row contains measurement labels, and info specifies whether or not the short description of each measurement function should be printed before the result matrix. If results is DIP\_FALSE, the measurement values are not printed.

### **ARGUMENTS**

Data type	Name	Description
dip_Measurement	measurement	Measurement data structure
FILE *	fp	FILE pointer to which the results are saved
dipio_WriteTextFormat	options	Text formatting options

The structure dipio\_WriteTextFormat contains the following elements:

Data type	Name	Description
char *	separator	Column separator character
dip_Boolean	info	Write descriptio
dip_Boolean	labels	Write labels
dip_Boolean	results	Write values
dip_Boolean	labelAlign	Align columns

SEE ALSO

Measure, MeasurementWrite

# Median

statistics function

### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Median ( in, mask, out, ps )
```

### DATA TYPES

binary, integer, float, complex

### **FUNCTION**

Calculates the median of the pixel values over all those dimensions which are specified by ps.

# **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
dip_Image	mask (0)	Mask
dip_Image	out	Output
dip_BooleanArray	ps (0)	Dimensions to project

# **SEE ALSO**

From images to scalars

Sum, Mean, Variance, StandardDeviation, MeanModulus, SumModulus, MeanSquareModulus, Maximum, Minimum, Percentile

# MedianFilter

Non-linear smoothing filter

### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_MedianFilter ( in, out, se, boundary, filterParam, shape )
```

### DATA TYPES

integer, float

### **FUNCTION**

Median filter with different structuring elements.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

# **SEE ALSO**

PercentileFilter, Uniform, Sigma

# ${\tt MemoryCopy}$

Copy memory blocks

# **SYNOPSIS**

void dip\_MemoryCopy( in, out, number )

# **FUNCTION**

Copy a memory block

# **ARGUMENTS**

Data type	Name	Description
void *	in	pointer to memory source block
void *	out	pointer to memory destination block
dip_int	number	number of bytes to be copied

# NOTE

The behaviour of this function is undefined when the in and out blocks overlap.

# MemoryFree

Free a chunk of memory

# **SYNOPSIS**

dip\_Error dip\_MemoryFree( pointer )

# **FUNCTION**

Frees a chunk of memory.

# **ARGUMENTS**

Data type	Name	Description
void *	pointer	pointer to an allocated chunk of memory

# **SEE ALSO**

MemoryNew, MemoryReallocate, MemoryFunctionsSet

# MemoryFunctionsSet

Sets memory allocation functions

### **SYNOPSIS**

### **FUNCTION**

Sets the memory allocation functions used by DIPlib.

### **ARGUMENTS**

Data type	Name	Description
dip_MemoryNewFunction	MemoryNewFunction	pointer to a memory
		allocation function
dip_MemoryReallocateFunction	MemoryReallocateFunction	pointer to a memory
		reallocation function
dip_MemoryFreeFunction	MemoryFreeFunction	pointer to a memory
		freeing function

### NOTE

The three allocation functions are defined as follows:

```
typedef void* (*dip_MemoryNewFunction)(size_t size)

# MemoryNew

491

Allocate and track memory

# **SYNOPSIS**

dip\_Error dip\_MemoryNew( pointer, size, resources )

# **FUNCTION**

Allocates a chunk of memory, and adds a reference to the chunk to the list of tracked resources.

# **ARGUMENTS**

Data type	Name	Description
void **	pointer	pointer to the memory chunk pointer
size_t	size	size of the memory chunk in bytes
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# **SEE ALSO**

MemoryReallocate, MemoryFree, MemoryFunctionsSet

# MemoryReallocate

Reallocate a chunk of memory

# **SYNOPSIS**

dip\_Error dip\_MemoryReallocate ( pointer, newsize, resources )

# **FUNCTION**

Reallocates a chunk of memory, to change its size. resources must be the dip\_Resources structure used in the call to MemoryNew when pointer was allocated.

### **ARGUMENTS**

Data type	Name	Description
void **	pointer	pointer to the memory chunk pointer
size_t	newsize	size of the memory chunk in bytes
dip_Resources	resources	Resources tracking structure. See ResourcesNew

Min

arithmetic function

### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Min ( in1, in2, out )
```

### DATA TYPES

binary, integer, float

### **FUNCTION**

This function computes out = min(in1, in2) on a pixel by pixel basis. The data types of the in1 and in2 image may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

# **ARGUMENTS**

Data type	Name	Description	
${\tt dip\_Image}$	in1	First input	
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input	
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output	

# **SEE ALSO**

Max, MaxFloat, MinFloat

# MinFloat

arithmetic function

### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_MinFloat ( in, out, constant )
```

### DATA TYPES

binary, integer, float

# **FUNCTION**

This function computes out = min(in, constant) on a pixel by pixel basis. The data types of the in1 image and constant may be of different types. See Information about dyadic operations for more information about what the type of the output will be.

### **ARGUMENTS**

Data type	Name	Description	
${\tt dip\_Image}$	in	Input	
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output	
dip_float	constant	Constant	

# **SEE ALSO**

Max, MaxFloat, Min

### Minima

Detects local minima

### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_Minima ( in, mask, out, connectivity, booleanOutput )
```

### DATA TYPES

integer, float

### **FUNCTION**

This function detects local minima.

The algorithm finds a connected set of pixels with identical value, an no neighbours with lower value. This set is a local minimum and its pixels are set to 1 in the output image. If booleanOutput is false, the output image is a labelled image.

This function differs from LocalMinima in that it marks every minimum. LocalMinima is able to filter out unimportant minima.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
dip_Image	mask	Mask image
${\tt dip\_Image}$	out	Binary output image
$\mathtt{dip\_int}$	connectivity	Connectivity
dip_Boolean	booleanOutput	Give a binary output image?

### NOTE

If you are looking for the old version of Minima, it is still available through the following combination of commands:

```
dip_Erosion( in, out, se, boundary, filterParam, shape );
dip_Equal( in, out, out );
```

# SEE ALSO

# Modulo

Arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Modulo ( in, out, period )
```

#### DATA TYPES

## integer

## **FUNCTION**

Computes the modulo of the input image values, by computing the remainder of the the division of the input image values with period.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	in	Input
dip_Image	out	Output
dip_int	period	Period

## **SEE ALSO**

Div, DivFloat, DivComplex, Reciprocal

# Modulus

## Arithmetic function

# **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Modulus ( in, out )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Computes the modulus of the input image values, and outputs a float typed image.

# **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

## **SEE ALSO**

Phase, Real, Imaginary

# MonadicFrameWork

FrameWork for monadic operations

#### **SYNOPSIS**

```
#include "dip_framework.h"
dip_Error dip_MonadicFrameWork ( in, out, processBoundary, processBorder, process )
```

#### **FUNCTION**

This function is a frontend on the SeparableFrameWork. It provides an easier interface for filters that only need to scan an image once. The dimension in which the image should be scan can be specified or left to MonadicFrameWork by specifying the dimension with DIP\_MONADIC\_OPTIMAL\_DIMENSION.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Boundary	processBoundary	ProcessBoundary
dip_int	processBorder	ProcessBorder
dip_FrameWorkProcess	process	Process

#### SEE ALSO

# ${\tt MorphologicalGradientMagnitude}$

Morphological edge detector

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_MorphologicalGradientMagnitude ( in, out, se, boundary,
filterParam, shape, edgeType )
```

#### DATA TYPES

 $integer,\,float\\$ 

#### **FUNCTION**

The same as MorphologicalRange.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output
$\mathtt{dip}_{-}\mathtt{Image}$	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape
dip_MphEdgeType	edgeType	edgeType

# **SEE ALSO**

 ${\tt Morphological Range, Lee, MultiScale Morphological Gradient, Tophat}$ 

# MorphologicalRange

Morphological edge detector

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_MorphologicalRange ( in, out, se, boundary, filterParam, shape,
edgeType )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Implements a morphological edge detector based on the difference of two complementary morphological operations. These can be chosen through the edgeType parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape
dip_MphEdgeType	edgeType	edgeType

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The enumerator  ${\tt dip\_MphEdgeType}$  contains the following constants:

Name	Description
DIP_MPH_TEXTURE	Response is limited to edges in texture
DIP_MPH_OBJECT	Response is limited to object edges
DIP_MPH_BOTH	All edges produce equal response

# SEE ALSO

# MorphologicalSmoothing

Morphological smoothing filter

#### **SYNOPSIS**

#include "dip\_morphology.h"
dip\_Error dip\_MorphologicalSmoothing ( in, out, se, boundary, filterParam, shape, flags )

#### DATA TYPES

integer, float

#### **FUNCTION**

Implements a morphological smoothing based on the sequence of two complementary morphological operations. These can be chosen through the dipf\_MphSmoothing parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape
dipf_MphSmoothing	flags	flags

517

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The enumerator  ${\tt dipf\_MphSmoothing}$  contains the following constants:

Name	Description
DIP_MPH_OPEN_CLOSE	First the opening, then the closing
DIP_MPH_CLOSE_OPEN	First the closing, then the opening
DIP_MPH_AVERAGE	The average of the result of the two above

# SEE ALSO

 ${\tt MorphologicalThreshold}, {\tt Tophat}$ 

# MorphologicalThreshold

Morphological smoothing filter

#### **SYNOPSIS**

#include "dip\_morphology.h"
dip\_Error dip\_MorphologicalThreshold ( in, out, se, boundary, filterParam, shape, edgeType )

#### DATA TYPES

integer, float

#### **FUNCTION**

Implements a morphological smoothing based on the average of two complementary morphological operations. These can be chosen through the edgeType parameter.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

# MultiScaleMorphologicalGradient

Morphological edge detector

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_MultiScaleMorphologicalGradient ( in, out, se, boundary,
upperSize, lowerSize, shape )
```

DATA TYPES

integer, float

#### **FUNCTION**

This function computes the average morphological gradient over a range of scales bounded by upperSize and lowerSize. The morphological gradient is computed as the difference of the dilation and erosion of the input image at a particular scale, eroded by an erosion of one size smaller. At the lowest scale, the size of the structuring element is 2 \* upperSize + 1.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, so is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

# **ARGUMENTS**

dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_int	upperSize	Upper size of structuring element
dip_int	lowerSize	Lower size of structuring element
dip_FilterShape	shape	Filter shape

The enumerator  ${\tt dip\_FilterShape}$  contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

## LITERATURE

D. Wang, Pattern Recognition, **30**(12), pp. 2043-2052, 1997

# **SEE ALSO**

# NearestInt

Arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_NearestInt ( in, out )
```

## DATA TYPES

binary, integer, float, complex binary, integer, float

## **FUNCTION**

Computes the nearest integer value of the input image values.

# **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
${\tt dip\_Image}$	out	Output

# **SEE ALSO**

Abs, Ceil, Floor, Sign, Truncate, Fraction

# ${\tt NeighbourIndicesListMake}$

Get indices to direct neighbours

#### **SYNOPSIS**

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourIndicesListMake ( stride, connectivity, indices, resources )
```

#### **FUNCTION**

A list indices is created with the relative indices to the direct neighbours of a pixel in an image whose strides are given by stride. How many direct neighbours are returned is controlled by connectivity, see The connectivity parameter for the available values and their meaning.

indices is allocated and tracked in resources.

#### **ARGUMENTS**

Data type	Name	Description
dip_IntegerArray	stride	Stride array
dip_int	connectivity	Connectivity
dip_IntegerArray *	indices	Output neighbour indices
dip_Resources	resources	Resources tracking structure. See ResourcesNew

#### **SEE ALSO**

NeighbourListMake, NeighbourListMakeChamfer, NeighbourListMakeImage, NeighbourListToIndices, NeighbourIndicesListMake

# NeighbourListMake

Get list of direct neighbours

#### **SYNOPSIS**

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListMake ( ndims, connectivity, coords, resources )
```

#### **FUNCTION**

A list coords is created with the relative coordinates to the direct neighbours of a pixel in an ndims-dimensional image. How many direct neighbours are returned is controlled by connectivity, see The connectivity parameter for the available values and their meaning. coords is allocated and tracked in resources.

#### **ARGUMENTS**

Data type	Name	Description
dip_int	ndims	Image dimensionality
dip_int	connectivity	Connectivity
dip_CoordinateArray *	coords	Output neighbour coordinates
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

## **SEE ALSO**

# NeighbourListMakeChamfer

Get list of neighbours based on Chamfer metric

#### **SYNOPSIS**

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListMakeChamfer ( pixelsize, maxdistance, coords,
distance, resources )
```

#### **FUNCTION**

A list coords is created with the relative coordinates to the neighbours of a pixel in an pixelsize->size-dimensional image. Here, neighbours are all pixels within a maxdistance distance. pixelsize gives the size of a pixel, and hence controls the size of the neighbourhood with maxdistance. Anisotropic pixel grids are supported. distance contains the distance to each of the neighbours in coords.

Distances between two pixels are taken to be the Euclidean distance. There are better metrics described in the literature for small neighbourhoods, that yield a more isotropic measure when compounded over longer distances. These are not implemented in this function.

coords and distance are allocated and tracked in resources.

#### **ARGUMENTS**

Data type	Name	Description
dip_FloatArray	pixelsize	Physical dimensions of the pixels
dip_int	maxdistance	Maximum distance to which select neighbours
dip_CoordinateArray *	coords	Output neighbour coordinates
dip_FloatArray *	distance	Output distances to neighbours
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

#### **SEE ALSO**

# NeighbourListMakeImage

Get list of neighbours based on metric in image

#### **SYNOPSIS**

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListMakeImage ( metric, coords, distance, resources )
```

#### **FUNCTION**

A list coords is created with the relative coordinates to the neighbours of a pixel in an image, with dimensionality as in metric. metric is an image that specifies the distance to each of the neighbours. This image must be odd in size, the centre pixel is the origin of the neighbourhood. Any pixel with value 0 is not considered part of the neighbourhood. distance contains the distance to each of the neighbours in coords.

Distances between two pixels are taken to be the Euclidean distance. There are better metrics described in the literature for small neighbourhoods, that yield a more isotropic measure when compounded over longer distances. These are not implemented in this function.

coords and distance are allocated and tracked in resources.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	metric	Image whose pixel values indicate the neighbour
		distance
dip_CoordinateArray *	coords	Output neighbour coordinates
dip_FloatArray *	distance	Output distances to neighbours
dip_Resources	resources	Resources tracking structure. See ResourcesNew

#### **SEE ALSO**

NeighbourListMake, NeighbourListMakeChamfer, NeighbourListMakeImage, NeighbourListToIndices, NeighbourIndicesListMake

# NeighbourListToIndices

Get indices to neighbours

#### **SYNOPSIS**

```
#include "dip_neighbourlist.h"
dip_Error dip_NeighbourListToIndices ( coords, stride, indices, resources )
```

#### **FUNCTION**

This function translates the relative coordinates in coords into relative indices into an image with strides given by stride.

indices is allocated and tracked in resources.

#### **ARGUMENTS**

Data type	Name	Description
dip_CoordinateArray	coords	Input neighbour coordinates
dip_IntegerArray	stride	Stride array
dip_IntegerArray *	indices	Output neighbour indices
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# NormaliseSum

Normalise the sum of the pixel values

## **SYNOPSIS**

```
#include "dip_math.h" #include "dip_manipulation.h"
dip_Error dip_NormaliseSum ( in, out, newSum )
```

## DATA TYPES

binary, integer, **float** 

#### **FUNCTION**

This function normalizes the sum of the pixel values in in to newSum, and puts the result in out.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input image
${\tt dip\_Image}$	out	Output image
dip_float	newSum	New sum

# NotEqual

Compare grey values in two images

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_NotEqual ( in1, in2, out )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function sets each pixel in out to "true" when corresponding pixels in in1 and in2 are different. This is the same as Compare with the DIP\_SELECT\_NOT\_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to the functionality of NotZero, but with more options.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in1	First input
dip_Image	in2	Second input
dip_Image	out	Output

#### **SEE ALSO**

Compare, Threshold, Equal, Greater, Lesser, NotGreater, NotLesser, SelectValue, NotZero

# NotGreater

537

Compare grey values in two images

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_NotGreater ( in1, in2, out )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function sets each pixel in out to "true" when for corresponding pixels  $in1 \le in2$ . This is the same as Compare with the DIP\_SELECT\_LESSER\_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in1	First input
dip_Image	in2	Second input
dip_Image	out	Output

#### **SEE ALSO**

Compare, Threshold, Equal, Greater, Lesser, NotEqual, NotLesser, SelectValue, NotZero

## NotLesser

Compare grey values in two images

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_NotLesser ( in1, in2, out )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function sets each pixel in out to "true" when for corresponding pixels in1 >= in2. This is the same as Compare with the DIP\_SELECT\_GREATER\_EQUAL selector flag.

in 2 can be a 0D image for comparison of pixel values with a single scalar value. This leads to a functionality similar to that of Threshold.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	in1	First input
dip_Image	in2	Second input
dip_Image	out	Output

#### **SEE ALSO**

 ${\tt Compare, Threshold, Equal, Greater, Lesser, NotEqual, NotGreater, SelectValue, NotZero}$ 

# NotZero

Point Operation

## **SYNOPSIS**

```
#include "dip_point.h"
dip_Error dip_NotZero ( in, out )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

This function returns a binary image with value 1 where in != 0 and value 0 elsewhere. The opposite can be accomplished with SelectValue: dip\_SelectValue(in,out,0);.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image

## **SEE ALSO**

Threshold, SelectValue, Compare, RangeThreshold

# ObjectToMeasurement

Convert object label value to measurement value

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_ObjectToMeasurement ( object, intensity, out, connectivity, objectID, featureID, measurementDim )
```

#### DATA TYPES

objectIm: integer intensityIm: integer, float

#### **FUNCTION**

This function produces an output image which pixel intensities are equal to the measurement value that the featureID measurement function measured on the object who label is defined by the pixel intensity of the corresponding pixel in object. This function is therefore useful to select (i.e. threshold) objects on basis of a measurement perfomed on the object. intensity provides pixel intensity information for measurements that require pixel intensity information of the objects, whose shape is defined by object.

The list of object IDs on which the measurements have to be performed is specified by objectID. If it is zero, ObjectToMeasurement will call GetObjectLabels to obtain a list of all non-zero values in objectIm.

If the featureID measurement function produces an array of measurement values, measurementDim will be used to select the desired array element.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	object	Object label image
$\mathtt{dip}_{-}\mathtt{Image}$	intensity	Object intensity image
$dip_{-}Image$	out	Output image
dip_int	connectivity	Connectivity of object's contour pixels, see The
		connectivity parameter
dip_IntegerArray	objectID	Array of Object IDs
dip_int	featureID	Measurement function ID
dip_int	measurementDim	Measurement results array index

		_	Λ.		$\sim$
S	⊢.	_	Δ	l S	.( )

 ${\tt Measure}, {\tt SmallObjectsRemove}, {\tt MeasurementToImage}, {\tt MeasurementToHistogram}$ 

## OneDimensionalSearch

Numerical algorithm

### **SYNOPSIS**

```
#include "dip_numerical.h"
dip_Error dip_OneDimensionalSearch ( result, min, max, tol, func, dfunc,
data, searchfor )
```

### **FUNCTION**

This function implements a numerical line-search for either the minimum or zero-crossing of a function. The obejctive is searched for in the range specified by min and man with a tolerance of tol. The search methods are based on Brent's algorithm. The dfunc parameter is preparation for support of search algorithms using derivative information. This is not supported in the current implementation, and dfunc should be set to zero.

#### **ARGUMENTS**

Data type	Name	Description
dip_float *	result	Result value
dip_float	min	Minimum value of search domain
dip_float	max	Maximum value of search domain
dip_float	tol	Tolerance
dip_OneDimensionalSearchFunction	func	Function
dip_OneDimensionalSearchFunction	dfunc	Derivative function
void *	data	User-supplied Data passed to func
		and dfunc
dipf_OneDimensionSearch	searchfor	Search for minimum of
		zero-crossing

DIP*lib* function reference

# Opening

Morphological opening operation

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_Opening ( in, out, se, boundary, filterParam, shape )
```

#### DATA TYPES

integer, float, binary

#### **FUNCTION**

Grey-value opening with different structuring elements.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# **SEE ALSO**

Closing, Dilation, Erosion

DIPlib function reference

0r

logic operation

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Or ( in1, in2, out )
```

## DATA TYPES

binary, integer

# **FUNCTION**

The function Or performs the logic OR operation between the corresponding pixels in in1 and in2, and stores the result in out.

# **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in1	First binary input image
dip_Image	in2	Second binary input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image

## **SEE ALSO**

And, Xor, Invert

ovl.h

Call an overloaded function

#### **SYNOPSIS**

```
dip_DataType ovlDataType = [current data type];
[#define DIP_OVL_ASSIGN [assignment target]]
#define DIP_OVL_FUNC [function base name]
#define DIP_OVL_ARGS [argument list]
#define DIP_OVL_ALLOW [type identifiers]
#include "dip_ovl.h"
```

#### **FUNCTION**

Call a type specific function based on the data type stored in the ovlDataType variable. The base name of the function is passed to dip\_ovl.h by defining DIP\_OVL\_FUNC. The argument list is passed by defining DIP\_OVL\_ARGS. By defining DIP\_OVL\_ALLOW the list of data types for which overloading is possible can be controlled. If DIP\_OVL\_ALLOW is not defined, all data types are allowed. The list is specified by a logical OR of identifier and identifier group flags, see the table at DIPlib's data types. The code executed by dip\_ovl.h is the following:

```
/* if ovlDataType is in the list specified by DIP_OVL_ALLOW */
DIPXJ( DIP_FUNC(DIP_OVL_FUNC,ovlDataType's extension) DIP_OVL_ARGS );
/* if ovlDataType is not in the list specified by DIP_OVL_ALLOW */
DIPSJ( DIP_E_DATA_TYPE_NOT_SUPPORTED );
```

DIP\_FUNC is described in macros.h. Note that there are no brackets around DIP\_OVL\_ARGS, so they must be included in DIP\_OVL\_ARGS itself. If ovlDataType is one of the binary types, DIP\_OVL\_BINARY\_ARGS can be defined to override DIP\_OVL\_ARGS.

If DIP\_OVL\_ASSIGN is defined, the following code will be executed by dip\_ovl.h instead of the code shown above:

```
DIP_OVL_ASSIGN DIP_FUNC(DIP_OVL_FUNC, ovlDataType's extension) DIP_OVL_ARGS;
```

Note that to actually perform an assignment the "=" operator must be included in the definition of DIP\_OVL\_ASSIGN itself. DIP\_OVL\_BINARY\_ASSIGN overrides DIP\_OVL\_ASSIGN if ovlDataType is one of the binary data types.

# PaintBox

Paint a box

### **SYNOPSIS**

```
#include "dip_paint.h"
dip_Error dip_PaintBox ( im, length, orign, amplitude )
```

### DATA TYPES

binary, integer, **float**, complex

### **FUNCTION**

Paints an box object in the image by replacing the values of the pixels in im that lie within the box (as specified by length and origin) with amplitude, and leaving the other pixel values untouched.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	im	Image
dip_FloatArray	length	Length array
dip_FloatArray	origin	Origin array
dip_float	amplitude	Pixel value of the painted ellips

# SEE ALSO

PaintEllipsoid, PaintDiamond

# PaintDiamond

Paint a diamond-shaped object

### **SYNOPSIS**

```
#include "dip_paint.h"
dip_Error dip_PaintDiamond ( im, length, orign, amplitude )
```

### DATA TYPES

binary, integer, **float**, complex

## **FUNCTION**

Paints a diamond-shaped object in the image by replacing the values of the pixels in im that lie within the diamond (as specified by length and origin) with amplitude, and leaving the other pixel values untouched.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	im	Image
dip_FloatArray	length	Length array
dip_FloatArray	origin	Origin array
dip_float	amplitude	Pixel value of the painted ellips

## **SEE ALSO**

PaintEllipsoid, PaintBox

# PaintEllipsoid

Paint an ellipsoid

### **SYNOPSIS**

```
#include "dip_paint.h"
dip_Error dip_PaintEllipsoid ( im, radius, orign, scale, amplitude )
```

### DATA TYPES

binary, integer, **float**, complex

### **FUNCTION**

Paints an elliptical object in the image by replacing the values of the pixels in im that lie within the ellips (as specified by diameter and origin) with amplitude, and leaving the other pixel values untouched.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	im	Image
dip_FloatArray	radius	Diameter array
dip_FloatArray	origin	Origin array
dip_float	amplitude	Pixel value of the painted ellips

# PairCorrelation

Compute the pair correlation function

#### **SYNOPSIS**

#include "dip\_analysis.h"
dip\_Error dip\_PairCorrelation ( object, mask, dist, probes, length, sampling,
covariance )

### DATA TYPES

binary, integer

#### **FUNCTION**

This function computes the pair correlation function of the different phases in object. If object is a binary image, the image is a regarded as a two phase image. In case object is of the integer type, the image is regarded as a labeled image, with each integer value encoding a phase. Optionally a mask image can be provided to select which pixels in object should be used to compute the pair correlation. The probes variable specifies how many random point pairs should be drawn to compute the function. Length specifies the maximum correlation length. The correlation function can be computed using a random (DIP\_CORRELATION\_ESTIMATOR\_RANDOM) or grid method (DIP\_CORRELATION\_ESTIMATOR\_GRID), as specified by sampling. Finally covariance

(DIP\_CORRELATION\_ESTIMATOR\_GRID), as specified by sampling. Finally covariance determines whether only the correlations (DIP\_FALSE) or the covarianances (DIP\_TRUE) have to be computed.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	object	Object image
$dip_{-}Image$	mask	Mask image
dip_Distribution	dist	Ouput distribution
dip_int	probes	Number of probes
dip_int	length	Maximum correlation Length
dipf_CorrelationEstimator	sampling	Samplings method
dip_Boolean	covariance	Compute covariance

SEE ALSO

 ${\tt ChordLength,\,ProbabilisticPairCorrelation}$ 

# PathOpening

Morphological filter

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error PathOpening ( grey, mask, out, length, closing, constrained )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function applies DirectedPathOpening in all possible directions and takes the supremum of all results. That is, it is the supremum of all possible openings with approximately linear structuring elements of length length.

The number of times that DirectedPathOpening is applied is given by ((3^D)-1)/2, with D the number of image dimensions. For example, in 2D there are 4 possible values for filterParam: [length,0], [0,length], [length,length] and [length,-length] (note that, for example, [-length,0] produces the same result as [length,0]).

See DirectedPathOpening for more information.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	grey	Grey-value input image
dip_Image	mask	Mask image for ROI processing
dip_Image	out	Output image
dip_int	length	Length of structuring element (number of pixels)
dip_Boolean	closing	DIP_FALSE for path opening, DIP_TRUE for path closing
dip_Boolean	constrained	DIP_TRUE for constrained paths, DIP_FALSE for the original
		path opening algorithm

#### SEE ALSO

DirectedPathOpening, Opening, Closing, AreaOpening

## Percentile

statistics function

### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Percentile ( in, mask, out, percentile, ps )
```

### DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Calculates the perc percentile of the pixel values over all those dimensions which are specified by ps.

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	mask (0)	Mask
dip_Image	out	Output
dip_float	perc	Percentile
dip_BooleanArray	ps (0)	Dimensions to project

# SEE ALSO

## PercentileFilter

Rank-order filter

#### **SYNOPSIS**

#include "dip\_morphology.h"
dip\_Error dip\_PercentileFilter ( in, out, se, boundary, filterParam, shape,
percentile )

### DATA TYPES

integer, float

### **FUNCTION**

Rank-order or percentile filter with different filter shapes.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape
dip_float	percentile	Percentile (%)

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

# PhysicalDimensionsFree

Free a Physical Dimensions data structure

## **SYNOPSIS**

```
#include "dip_support.h"
dip_Error dip_PhysicalDimensionsFree ( physDims )
```

### **FUNCTION**

This function free the Physical Dimensions physDims structure.

### **ARGUMENTS**

Data type	Name	Description
dip_PhysicalDimensions *	physDims	Physical Dimensions data structure

## **SEE ALSO**

Physical Dimensions New, Physical Dimensions Copy, Physical Dimensions Is I so tropic

# PhysicalDimensionsIsIsotropic

Checks if the Physical Dimensions are isotropic

### **SYNOPSIS**

```
#include "dip_support.h"
dip_Error dip_PhysicalDimensionsIsIsotropic ( physDims, verdict )
```

### **FUNCTION**

This function checks whether the physical dimensions physDims are isotropic by checking that all its pixel dimensions and dimension units are equal to each other. If verdict is not zero, the result (DIP\_TRUE or DIP\_FALSE) is stored in verdict, otherwise an error is returned in case the verification fails.

### **ARGUMENTS**

Data type	Name	Description
dip_PhysicalDimensions	physDims	Physical Dimensions data structure
dip_Boolean *	verdict	Verdict of the test

### SEE ALSO

PhysicalDimensionsNew, PhysicalDimensionsFree, PhysicalDimensionsCopy

# PhysicalDimensionsNew

561

Allocates a new Physical Dimensions structure

#### **SYNOPSIS**

```
#include "dip_support.h"
dip_Error dip_PhysicalDimensionsNew ( newPhysDims, dimensionality, dims,
orig, dimUnit, intensity, offset, intensUnit, resources )
```

### **FUNCTION**

This function allocates a new Physical Dimensions structure.

A physical dimensions structure contains information about the physical dimensions of the data (of dimensionality dimension) in an image. It describes the position (orig) and size (dims) of a pixel in world coordinates and physical units (dimUnits), as well as the scaling (intensity) and offset (offset) of the pixel intensity in physical units (intensUnit).

Note that the initial values assigned by this function assume an isotropic pixel size. These values can be changed within the structure generated if this is not the case.

#### **ARGUMENTS**

Data type	Name	Description
dip_PhysicalDimensions *	newPhysDims	Pointer to a new Physical Dimensions
		data structure
dip_int	dimensionality	Dimensionality of the image
dip_float	dims	Initial value for dimensions along all
		axes
dip_float	orig	Initial value for origin along all axes
char *	dimUnit	Initial value for dimensionUnits along
		all axes
dip_float	intensity	Initial value for intensity
dip_float	offset	Initial value for offset
char *	intensUnit	Initial value for intensityUnit
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

The structure dip\_PhysicalDimensions contains the following elements:

Data type	Name	Description
dip_FloatArray	dimensions	Dimensions of a pixel along each grid axis
dip_FloatArray	origin	Coordinates of the origin in physical units
dip_StringArray	dimensionUnits	Units for dimensions and origin
dip_float	intensity	Intensity scaling in physical units
dip_float	offset	Offset for intensity in physical units
dip_String	intensityUnit	Units for intensity and offset
dip_Resources	resources	Resource tracking; all elements within this
		structure are tracked here

# PixelHeapIsEmpty

Query heap

## **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapIsEmpty ( heap, result )
```

### **FUNCTION**

Checks to see if there are any items on the heap. See PixelHeapNew for information on the heap data structure.

### **ARGUMENTS**

Data type	Name	Description
dip_PixelHeap	heap	The heap structure
dip_Boolean *	result	Set to true if there are no items in the heap

# **SEE ALSO**

PixelHeapNew, StablePixelHeapNew, PixelQueueNew, PixelHeapFree, PixelHeapPush, PixelHeapPop

# PixelHeapNew

Create a new heap structure

### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapNew ( heap, ndims, blocksize, order, resources )
```

#### **FUNCTION**

This function allocates space for a new dip\_PixelHeap structure. Memory allocated is tracked in resources. The heap is dimensioned to hold pixels from an ndims-dimensional image, and initially enough space is allocated for blocksize elements. The heap will be expanded as necessary when used.

The heap stores the coordinates, the value and the pointer to a pixel in an image. Note that the value does not need to equal the data pointed to by the pointer. ndims can be set to zero, in which case no coordinates are stored; this does not affect the function of the value and the pointer.

A heap is a priority queue data structure. Just like a queue, items can be added (pushed) and subtracted (popped). However, in the priority queue the item popped is always the higherst priority one: either the one with the highest-valued item (order is DIP\_GVSO\_HIGH\_FIRST) or lowest-valued item (order is DIP\_GVSO\_LOW\_FIRST). However, identically-valued items are stored on the heap in unpredictable order. If this order is important (such as for the GrowRegions algorithm with integer-valued pixels, use a dip\_StablePixelHeap instead. See StablePixelHeapNew for information on the stable heap structure.

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelHeap *	heap	The newly allocated heap structure
dip_int	ndims	Image dimensionality
dip_int	blocksize	Size of each allocation block
dipf_GreyValueSortOrder	order	Determines the heap's sort order
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

The dipf\_GreyValueSortOrder enumeration consists of the following values:

Name	Description
DIP_GVSO_HIGH_FIRST	Process the pixels from high grey-value to low grey-value.
DIP_GVSO_LOW_FIRST	Process the pixels from low grey-value to high grey-value.

## **IMPLEMENTATION**

When the heap grows beyond its initial size, its capacity is doubled in size by reallocating the data blocks. However, when removing pixels from the queue, the heap is not shrunk. It is assumed that the dip\_PixelHeap structure will be destroyed as soon as the algorithm using it terminates. Reducing the memory footprint of the heap therefore has no benefit.

## SEE ALSO

 ${\tt StablePixelHeapNew,\ PixelQueueNew,\ PixelHeapFree,\ PixelHeapPush,\ PixelHeapPop,\ PixelHeapIsEmpty}$ 

# PixelHeapPop

Pop item onto heap

#### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapPop ( heap, coords, pointer, value )
```

### **FUNCTION**

Pops the next pixel from the heap. See PixelHeapNew for information on the heap data structure. coords is a pointer to an array of dip\_ints, such as that obtained with dip\_IntegerArray->array. It should have as many elements as the image dimensionality. If the stack was created with ndims set to 0, the coords pointer is ignored. coords, pointer and value can be NULL if you are not interested in either those values.

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelHeap	heap	The heap structure
dip_int *	coords	Receives the coordinates of the popped item
void **	pointer	Receives the pointer of the popped item
dip_sfloat *	value	Receives the value of the popped item

### **SEE ALSO**

# PixelHeapPush

Push item onto heap

### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelHeapPush ( heap, coords, pointer, value )
```

### **FUNCTION**

Pushes a pixel onto the heap. See PixelHeapNew for information on the heap data structure. All 3 values coords, pointer and value are stored, except if the heap was created with ndims set to 0, in which case the coords pointer is ignored.

coords is a pointer to an array of dip\_ints, such as that obtained with dip\_IntegerArray->array. It should have as many elements as the image dimensionality. pointer is a pointer to any memory location, and value is the value to be used when sorting.

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelHeap	heap	The heap structure
dip_int *	coords	Coordinates to be pushed
void *	pointer	Pointer to be pushed
dip_sfloat	value	Value to be pushed

# PixelQueueFree

Destroy queue structure

## **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueueFree ( queue )
```

### **FUNCTION**

Frees all data associated to queue and sets queue to 0.

## **ARGUMENTS**

Data type	Name	Description
dip_PixelQueue *	queue	The queue structure

## **SEE ALSO**

PixelQueueNew, PixelHeapNew, StablePixelHeapNew, PixelQueuePush, PixelQueuePop, PixelQueueIsEmpty

# PixelQueueIsEmpty

Query queue

## **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueueIsEmpty ( queue, result )
```

### **FUNCTION**

Checks to see if there are any items on the queue. See PixelQueueNew for information on the queue data structure.

### **ARGUMENTS**

Data type	Name	Description
dip_PixelQueue	queue	The queue structure
dip_Boolean *	result	Set to true if there are no items in the queue

## **SEE ALSO**

PixelQueueNew, PixelHeapNew, StablePixelHeapNew, PixelQueueFree, PixelQueuePush, PixelQueuePop

# PixelQueueNew

Create a new queue structure

#### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueueNew ( queue, ndims, blocksize, resources )
```

#### **FUNCTION**

This function allocates space for a new dip\_PixelQueue structure. Memory allocated is tracked in resources. The queue is dimensioned to hold pixels from an ndims-dimensional image, and initially enough space is allocated for blocksize elements. The queue will be expanded as necessary when used.

The queue stores the coordinates, and the pointer to a pixel in an image. ndims can be set to zero, in which case no coordinates are stored; this does not affect the function of the pointer.

A queue is a data structure to which items can be added (pushed) to the back, and subtracted (popped) from the front (FIFO - First In, First Out).

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelQueue *	queue	The newly allocated queue structure
dip_int	ndims	Image dimensionality
dip_int	blocksize	Size of each allocation block
dip_Resources	resources	Resources tracking structure. See ResourcesNew

#### **IMPLEMENTATION**

The queue is stored in an array whose size can be incressed at will. This is accomplished by a linked list of blocks, each one holds blocksize elements. When more space is needed, a new block is simply allocated. No data needs to be moved as would be necessary when using realloc to change the size of the array. Blocks on the front of the queue that become empty are freed.

# SEE ALSO

 ${\tt Pixel Heap New,\ Stable Pixel Heap New,\ Pixel Queue Free,\ Pixel Queue Push,\ Pixel Queue Pop,\ Pixel Queue Is {\tt Empty}}$ 

# PixelQueuePop

Pop item from queue

### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueuePop ( queue, coords, pointer, newiteration )
```

#### **FUNCTION**

Pops the next pixel from the queue. See PixelQueueNew for information on the queue data structure. coords is a pointer to an array of dip\_ints, such as that obtained with dip\_IntegerArray->array. It should have as many elements as the image dimensionality. If the queue was created with ndims set to 0, the coords pointer is ignored. coords and pointer can be NULL if you are not interested in either those values.

newiteration, when not NULL, will be set to DIP\_TRUE if the pixel being popped is the first one in an iteration, or DIP\_FALSE otherwise. When a new iteration starts, all pixels pushed onto the queue afterwards belong to the next iteration. This is useful in routines that use the queue for propagating boundaries, such as <code>GrowRegions</code>. First all boundary pixels are pushed onto the queue. The first iteration will need to process only these pixels, while at the same time push new pixels onto the queue for the second iteration. So after pushing all the initial boundary pixels onto the queue, the first iteration is started by popping the first pixel. All pixels pushed while processing this and the rest of the pixels will be pushed behind the "new iteration" marker. When the first pixel after this marker is popped, the newiteration boolean is set, so the program knows that the second iteration is starting. Also, the "new iteration" marker is moved to the end of the queue, so that pixels pushed subsequently will belong to iteration number 3.

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelQueue	queue	The queue structure
dip_int *	coords	Receives the coordinates of the popped item
void **	pointer	Receives the pointer of the popped item
dip_Boolean *	newiteration	Set to true when the first item from an iteration is
		popped

# SEE ALSO

 $\label{thm:pixelQueue} PixelQueueNew, PixelQueueFree, PixelQueuePush, PixelQueueIsEmpty$ 

# PixelQueuePush

Push item onto queue

### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_PixelQueuePush ( queue, coords, pointer )
```

### **FUNCTION**

Pushes a pixel onto the queue. See PixelQueueNew for information on the queue data structure. Both coords and pointer are stored, except if the stack was created with ndims set to 0, in which case the coords values are ignored.

coords is a pointer to an array of dip\_ints, such as that obtained with
dip\_IntegerArray->array. It should have as many elements as the image dimensionality.
pointer is a pointer to any memory location.

### **ARGUMENTS**

Data type	Name	Description
dip_PixelQueue	queue	The queue structure
dip_int *	coords	Coordinates to be pushed
void *	pointer	Pointer to be pushed

## PixelTableAddRun

Add a new run to a pixel table

### **SYNOPSIS**

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableAddRun ( table, coordinate, length )
```

### **FUNCTION**

Adds a new run to a pixel table. The new run is appended to the existing runs in the pixel table.

### **ARGUMENTS**

Data type	Name	Description
dip_PixelTable	table	Pixel table
dip_IntegerArray	coordinate	Coordinate of the run
dip_int	length	Length of the run

### **SEE ALSO**

Description of DIPlib's pixel tables

# PixelTableCreateFilter

Create a pixel table from a filter shape

#### **SYNOPSIS**

#include "dip\_pixel\_table.h"
dip\_Error dip\_PixelTableCreateFilter ( table, filterSize, filterShape, se, resources)

## **FUNCTION**

This function allocates and creates a new pixel table data structure. The shape and dimensionality of the pixel table is specified by the filterSize, filterShape and se parameters.

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelTable *	table	Pointer to a pixel table
dip_FloatArray	filterSize	Filter size
dip_FilterShape	filterShape	Filter shape
dip_Image	se	Structuring element
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# PixelTableFrameWork

FrameWork for PixelTable filters

# **SYNOPSIS**

```
#include "dip_framework.h" #include "dip_tprunlength.h"
dip_Error dip_PixelTableFrameWork ( in, out, boundary, process, table )
```

## **FUNCTION**

This function provides a framework for filters that code the shape of their filter in a pixel table (runlengths). See SeparableFrameWork for details.

# **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_BoundaryArray	boundary	Boundary conditions
dip_FrameWorkProcess	process	Process
dip_PixelTable	table	Pixel table

# PixelTableGetDimensionality

Get the dimensionality of a pixel table

#### **SYNOPSIS**

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetDimensionality ( table, dimension )
```

## **FUNCTION**

Gets the dimensionality of the binary object that is encoded by the pixel table table.

## **ARGUMENTS**

Data type	Name	Description
dip_PixelTable	table	pixel table
dip_int *	dimension	pointer to a dimensionality variable

## **SEE ALSO**

Description of DIPlib's pixel tables

PixelTableNew, PixelTableSetRun, PixelTableGetRun, PixelTableGetOrigin, PixelTableGetSize, PixelTableGetPixelCount, PixelTableGetOffsetAndLength

# PixelTableGetDimensions

Get the dimemsions of a pixel table

## **SYNOPSIS**

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetDimensions ( table, dimensions, resources )
```

## **FUNCTION**

This functions gets the dimensions of the bounding box of the binary object that is encoded by the pixel table table.

## **ARGUMENTS**

Data type	Name	Description
dip_PixelTable *	table	Pixel table
dip_IntegerArray *	dimensions	Pointer to a dimensions array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

Description of DIPlib's pixel tables

PixelTableNew, PixelTableSetRun, PixelTableGetRun, PixelTableAddRun, PixelTableGetRuns, PixelTableGetOrigin, PixelTableGetSize, PixelTableGetPixelCount, PixelTableGetOffsetAndLength

# PixelTableGetOffsetAndLength

Converts the pixel table's runs

#### **SYNOPSIS**

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableGetOffsetAndLength ( table, stride, offset, length, resources )
```

## **FUNCTION**

This functions converts the linked-list of runs in the pixel table to two arrays of offsets and lengths. The length of these arrays equals the number of runs. The offsets are calculated by multiplying each coordinate of a run with the stride of that dimension. This function is useful when an image needs to be filtered with a filter that is encoded by a pixel table. Before processing the image. See also PixelTableFrameWork.

#### **ARGUMENTS**

Data type	Name	Description
dip_PixelTable	table	Pixel table
dip_IntegerArray	stride	Stride array
dip_IntegerArray *	offset	Pointer to offset array
dip_IntegerArray *	length	Pointer to length array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# PixelTableSetRun

Initialises a pixel table run

#### **SYNOPSIS**

```
#include "dip_pixel_table.h"
dip_Error dip_PixelTableSetRun ( table, run, coordinate, length )
```

## **FUNCTION**

This function initialises the runth run of the pixel table table, by setting the run's coordinate to coordinate and its length to length. The pixel table must at least consist of run number of runs and has to be allocated (using PixelTableNew).

## **ARGUMENTS**

Data type	Name	Description
dip_PixelTable	table	Pixel table
dip_int	run	The run to be initialised
dip_IntegerArray	coordinate	Coordinate of the run
dip_int	length	Length of the run

# PoissonNoise

Generate an image disturbed by Poisson noise

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_PoissonNoise ( in, out, conversion, random )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Generate a Poisson noise disturbed image. The intensities of the input image divided by the conversion variable are used as mean value for the Poisson distribution. The conversion factor can be used to relate the pixel values with the number of counts. For example, the simulate a photon limited image acquired by a CCD camera, the conversion factor specifies the relation between the number of photons recorded and the pixel value it is represented by.

See PoissonRandomVariable for more information on the random number generator.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
dip_Image	out	Output
dip_float	conversion	Conversion factor (photon/ADU)
dip_Random *	random	random

#### **EXAMPLE**

Get a Poisson disturbed image as follows:

```
dip_Image in, out;
dip_float conversion;
dip_Random random;

conversion = 2.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_PoissonNoise( in, out, conversion, &random ));
```

# SEE ALSO

 $\label{thm:poissonRandomVariable} PoissonRandomVariable, RandomSeed, RandomSeedVector, \\ UniformNoise, GaussianNoise, BinaryNoise$ 

# PoissonRandomVariable

Poisson random variable generator

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_PoissonRandomVariable ( random, mean, value )
```

#### **FUNCTION**

PoissonRandomVariable uses the algorithm as described in "Numerical Recipes in C, 2nd edition", section 7.3. For values of mean larger or equal to 32 the rejection method is used.

See RandomVariable for more information on the random number generator.

#### **ARGUMENTS**

Data type	Name	Description
dip_Random *	random	Pointer to a random value structure
dip_float	mean	Mean value for the distribution
dip_float *	value	Poisson distributed output value

#### **EXAMPLE**

Get a Poisson random variable as follows:

```
dip_Random random;
dip_float mean, value;

mean = 23.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_PoissonRandomVariable( &random, mean, &value ));
```

# ProbabilisticPairCorrelation

Compute the probabilistic pair correlation function

#### **SYNOPSIS**

#include "dip\_analysis.h"
dip\_Error dip\_ProbabilisticPairCorrelation ( phases, mask, dist, probes,
length, sampling, covariance )

#### DATA TYPES

#### float

#### **FUNCTION**

This function computes the probabilistic pair correlation function of the different phases in phases. Each image in the image array phases is treated as a separate phase. The function assumes, but does not check, that the values in these images are with the [0 1] range. Optionally a mask image can be provided to select which pixels in object should be used to compute the pair correlation. The probes variable specifies how many random point pairs should be drawn to compute the function. Length specifies the maximum correlation length. The correlation function can be computed using a random

(DIP\_CORRELATION\_ESTIMATOR\_RANDOM) or grid method

(DIP\_CORRELATION\_ESTIMATOR\_GRID), as specified by sampling. Finally covariance determines whether only the correlations (DIP\_FALSE) or the covarianances (DIP\_TRUE) have to be computed.

#### **ARGUMENTS**

Data type	Name	Description
$ extstyle{dip\_ImageArray}$	phases	Phase image array
dip_Image	mask	Mask image
dip_Distribution	dist	Ouput distribution
dip_int	probes	Number of probes
dip_int	length	Maximum chord length
dipf_CorrelationEstimator	sampling	Samplings method
dip_Boolean	covariance	Compute covariance

SEE ALSO

PairCorrelation, ChordLength

# PseudoInverse

Image restoration filter

## **SYNOPSIS**

```
#include "dip_restoration.h"
dip_Error dip_PseudoInverse ( in, psf, out, threshold, flags )
```

## **FUNCTION**

This function performs a basic, very noise sensitive image restoration operation by inverse filtering the image with a clipped point spread function. Each frequency in the output for which the response of the PSF is smaller than threshold is set to zero.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
$dip_{-}Image$	psf	Point spread function image
dip_Image	out	Output image
dip_float	threshold	Threshold value
dipf_Restoration	flags	Restoration flags

# PutLine

Put a line in an image

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_PutLine ( in, out, cor, dimension )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Put a line in an image. Put a line orthogonally in an image. The position of the line in the image is specified by the coordinates at which its left most pixel (cor) is be placed and on which dimension of the image, the dimension of the line maps (dimension). If in has a different type than out, it will be converted to the type of out.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input Line Image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output Image
dip_IntegerArray	cor	Coordinate in the image of the left most pixel of the
		line
dip_int	dimension	Dimension of the image on which the line's dimension
		maps

## **SEE ALSO**

GetSlice, PutSlice, GetLine

# PutSlice

Put a slice in an image

## **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_PutSlice ( in, out, cor, dim1, dim2 )
```

## DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Put a slice orthogonally in an image. The position of the slice in the image is specified by the coordinates at which its upper left corner (cor) should be placed and on which dimensions of the image, the dimensions of the slice map (dim1, dim2). If in has a different type than out, it will be converted to the type of out.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	2D Input Image
dip_Image	out	3D Output Image
dip_IntegerArray	cor	Coordinate in out where the upper left corner of in is
		placed
dip_int	dim1	Dimension of in on which the slice's first dimension maps
dip_int	dim2	Dimension of in on which the slice's second
		dimensionmaps

# **SEE ALSO**

 ${\tt QuickSortIndices}, {\tt QuickSortIndices16}, {\tt Sort, ImageSort}, {\tt SortIndices}, {\tt SortIndices16}, {\tt ImageSortIndices}$ 

# QuickSortAnything

Sort data of any type

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_QuickSortAnything ( data, size, compareFunction, swapFunction,
tmpData )
```

## **FUNCTION**

Sorts a block of data (of size size) using the quick sort algorithm. This routine requires the user to write two functions in order to fully implement the sorting procedure. These are SortCompareFunction and SortSwapFunction.

#### **ARGUMENTS**

Data type	Name	Description
void *	data	Data
dip_int	size	Size
$ ext{dip\_SortCompareFunction}$	compareFunction	Function for comparing two data
		points
dip_SortSwapFunction	swapFunction	Function for swapping two data points,
		or copying one to the other
void *	tmpData	Pointer to a variable of the same type
		as the data, used as temporary space
		by some of the algorithms

## **SEE ALSO**

General information about sorting

SortAnything, SortCompareFunction, SortSwapFunction

# RadialMaximum

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_RadialMaximum ( in, mask, out, ps, binSize, innerRadius, center
)
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function computes the radial projection of the maximum of the pixel intensities of in. The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the maximum of the intensities of all pixels with n \* binSize <= r < (n + 1) \* binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP\_TRUE, the maximum radius that is projected is equal to the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Binary mask (or 0)
dip_Image	out	Output
dip_BooleanArray	ps	Dimensions to project (or 0)
dip_float	binSize	Size of radial bins
dip_Boolean	innerRadius	Maximum radius
dip_FloatArray	center	Coordinates of center (or 0)

#### **SEE ALSO**

RadialSum, RadialMean, RadialMinimum, Sum, Mean, Maximum, Minimum

# RadialMean

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_RadialMean ( in, mask, out, ps, binSize, innerRadius, center )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function computes the radial projection of the mean of the pixel intensities of in.

The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the mean of the intensities of all pixels with n \* binSize <= r < (n + 1) \* binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP\_TRUE, the maximum radius that is projected is equal to the the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	mask	Binary mask (or 0)
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output
dip_BooleanArray	ps	Dimensions to project (or 0)
dip_float	binSize	Size of radial bins
dip_Boolean	innerRadius	Maximum radius
dip_FloatArray	center	Coordinates of center (or 0)

## **SEE ALSO**

RadialSum, RadialMaximum, RadialMinimum, Sum, Mean, Maximum, Minimum

# RadialMinimum

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_RadialMinimum ( in, mask, out, ps, binSize, innerRadius, center
)
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

This function computes the radial projection of the sum of the pixel intensities of in.

The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the minimum of the intensities of all pixels with n \* binSize <= r < (n + 1) \* binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP\_TRUE, the maximum radius that is projected is equal to the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Binary mask (or 0)
$dip_{-}Image$	out	Output
dip_BooleanArray	ps	Dimensions to project (or 0)
dip_float	binSize	Size of radial bins
dip_Boolean	innerRadius	Maximum radius
dip_FloatArray	center	Coordinates of center (or 0)

#### **SEE ALSO**

# RadialSum

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_RadialSum ( in, mask, out, ps, binSize, innerRadius, center )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function computes the radial projection of the sum of the pixel intensities of in.

The radial projection is performed for the dimensions specified by ps. If the radial distance of a pixel to the center of the image is r, than the sum of the intensities of all pixels with n \* binSize <= r < (n + 1) \* binSize is stored at position n in the radial dimension of out. The radial dimension is the first dimension to be processed (as specified by ps). If innerRadius is set to DIP\_TRUE, the maximum radius that is projected is equal to the the smallest dimension of the to be projected dimensions. Otherwise, the maximum radius is set equal to the diagonal length of the dimensions to be processed.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	mask	Binary mask (or 0)
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output
dip_BooleanArray	ps	Dimensions to project (or 0)
dip_float	binSize	Size of radial bins
dip_Boolean	innerRadius	Maximum radius
dip_FloatArray	center	Coordinates of center (or 0)

# RandomSeed

Initialise random number generator

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_RandomSeed ( random, seed )
```

## **FUNCTION**

Initializes a dip\_Random structure using a given seed value. If seed is 0, the default value of 5489 is used instead, since 0 produces a uniquely poor initialisation.

## **ARGUMENTS**

Data type	Name	Description
dip_Random *	random	Pointer to a random value structure
dip_uint32	seed	Seed value

#### **EXAMPLE**

Initialize a dip\_Random structure as follows:

```
dip_Random random;
dip_uint32 seed;
seed = 123758;
DIPXJ( dip_RandomSeed( &random, seed ));
```

## SEE ALSO

# RandomSeedVector

Initialise random number generator

## **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error RandomSeedVector ( random, seedvector )
```

## **FUNCTION**

Initializes a dip\_Random structure with a given seed value vector. The vector must have DIP\_MT\_STATE\_SIZE (==624) values. This is an alternative to RandomSeed, which, by initialising with a 32-bit integer, only gives 4 billion different sequences. RandomSeedVector allows to initialise the whole status of the random number generator.

## **ARGUMENTS**

Data type	Name	Description
dip_Random *	random	Pointer to a random value structure
dip_uint32[DIP_MT_STATE_SIZE]	seedvector	Seed value vector

#### SEE ALSO

RandomSeed, RandomVariable, UniformRandomVariable, GaussianRandomVariable, PoissonRandomVariable, BinaryRandomVariable

DIP*lib* function reference 609

# RandomVariable

Random number generator

#### **SYNOPSIS**

```
include "dip_noise.h"
dip_Error dip_RandomVariable ( random, value )
```

#### **FUNCTION**

Generates a random number between zero and one. The dip\_Random structure must be initialized with the function RandomSeed. If the supplied dip\_Random structure is not initialized, RandomVariable will initialize the dip\_Random structure with the default seed. To guarantee the (psuedo) randomness between variables obtained with subsequent calls to RandomVariable (or to functions that use this function to obtain a random variable), a pointer to the same dip\_Random structure has to supplied when calling RandomVariable.

The random number generator returns random numbers as 32-bit integers, which are normalised to to [0,1] range. If higher precision numbers are required, you can set random.highprecision to DIP\_TRUE. This causes two random 32-bit values to be used for each floating point output value, doubling the precision of the output. There is no need to re-initialise the random structure after changing this setting.

This function is based on LGPL code by Geoff Kuenning (mtwist-0.8) implementing the Mersenne Twister pseudo-random number generator.

#### **ARGUMENTS**

Data type	Name	Description
dip_Random *	random	Pointer to a random value structure
dip_float *	value	Random value

## **EXAMPLE**

Obtain a random number as follows:

```
dip_Random random;
dip_float val;

DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_RandomVariable( &random, &val ));
```

# RangeThreshold

Point Operation

#### **SYNOPSIS**

#include "dip\_point.h"

dip\_Error dip\_RangeThreshold ( in, out, lowerBound, upperBound, foreground, background, binaryOutput )

## DATA TYPES

integer, float

## **FUNCTION**

out = (lowerBound <= in <= upperBound? foreground: background) If the boolean binaryOutput is true, RangeThreshold will produce a binary image. Otherwise an image of the same type as the input image is produced, with the pixels set to either foreground or background.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
dip_Image	out	Output image
dip_float	lowerBound	Lower bound
dip_float	upperBound	Upper bound
dip_float	foreground	Foreground value
dip_float	background	Background value
dip_Boolean	binaryOutput	Convert output image to binary

## Register

Generic registry function

#### **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_Register ( register )
```

#### **FUNCTION**

The Registry functions Register, Unregister, RegisterClass, RegistryList, RegistryGet RegistryValid and RegistryArrayNew are the access functions for DIPlib's generic registry framework. These functions control the access to a registry containing information of items that are registered at run-time. Each item belongs to a certain class and is identified with an ID that is unique within the item's class.

DIPlib's Registry classes are registered at run-time as well (using RegisterClass) and should be registered before and item of that class can registered.

Although the generic Registry functions can be used to register, and obtain the data of registered items of a specific clas, it is more userfriendly to use class specific Registry functions like MsrRegister and companions.

The dip\_Register function accepts one argument, a dip\_Registry structure, which contains the ID and class of the to be registered data and registry, a pointer to class-specific data. Note that this pointer, registry, is freed when the (global) registry information is freed.

The following code gives an example of a class-specific register function:

```
dip_Error dip_MsrRegister
(
    dip_MsrRegistry registry
)
{
    DIP_FN_DECLARE("dip_MsrRegister");
    dip_Registry globalRegistry;
    void *data;
    dip_MsrRegistry *reg;

    switch( registry.type )
    {
        default:
            DIPSJ( DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
            break;
```

}

```
case DIP_MSR_FUNCTION_LINE_BASED:
         DIPTS( ! ( registry.create &&
              registry.measure.line &&
              registry.value &&
              registry.labels &&
              registry.description),
          DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
         break;
      case DIP_MSR_FUNCTION_IMAGE_BASED:
         DIPTS(! (registry.create &&
              registry.measure.image &&
              registry.value &&
              registry.labels &&
              registry.description),
          DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
         break;
      case DIP_MSR_FUNCTION_CHAINCODE_BASED:
         DIPTS( ! ( registry.create &&
              registry.measure.chaincode &&
              registry.value &&
              registry.labels &&
              registry.description),
          DIP_E_REGISTRY_INCOMPLETE_REGISTRY );
         break;
   }
   /* copy the Msr specific registry info */
   DIPXJ( dip_MemoryNew( &data, sizeof( dip_MsrRegistry ), 0 ));
   reg = data;
   *reg = registry;
   globalRegistry.id
                           = registry.id;
   globalRegistry.class
                           = DIP_REGISTRY_CLASS_MEASUREMENT;
   globalRegistry.registry = reg;
   /* register this measurement registry data */
   DIPXJ( dip_Register( globalRegistry ));
dip_error:
  DIP_FN_EXIT;
```

## **ARGUMENTS**

Data type	Name	Description
dip_Registry	registry	Generic registry structure

## SEE ALSO

 $\label{thm:continuous} \begin{tabular}{ll} Unregister, RegisterClass, RegistryList, RegistryGet, RegistryValid, RegistryArrayNew \end{tabular}$ 

# RegisterClass

Register a registry class

## **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_RegisterClass ( class )
```

## **FUNCTION**

This function registers a Registry class. See **Register** for more information about DIPlib's Registry.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{int}$	class	Registry class ID

## **SEE ALSO**

Register, Unregister, RegistryValid, RegistryList, RegistryGet, RegistryArrayNew

# RegistryArrayNew

Allocate a registry array

## **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_RegistryArrayNew ( array, size, resources )
```

## **FUNCTION**

This function allocates an array of dip\_Registry structures.

## **ARGUMENTS**

Data type	Name	Description
dip_RegistryArray *	array	Pointer to the allocated array
dip_int	size	Array size
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

Register, RegistryList, RegistryGet

# RegistryGet

619

Get a registry item

#### **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_RegistryGet ( id, class, registry )
```

#### **FUNCTION**

This function obtains the Registry information of the ID of the Registry class class. See Register for more information about DIPlib's Registry.

The following code gives an example of a class-specific register list function:

```
dip_Error dip_MsrRegistryGet
(
    dip_int id,
    dip_MsrRegistry *registry
)
{
    DIP_FN_DECLARE("dip_MsrRegistryGet");
    dip_MsrRegistry *reg;
    void *data;

    DIPXJ( dip_RegistryGet ( id, DIP_REGISTRY_CLASS_MEASUREMENT, &data ));
    reg = data;
    *registry = *reg;

dip_error:
    DIP_FN_EXIT;
}
```

#### **ARGUMENTS**

Data type	Name	Description	
$\mathtt{dip}_{\mathtt{-}}\mathtt{int}$	id	Registry ID	
dip_int	class	Registry class	
dip_void **	registry	Pointer to registered data	

# SEE ALSO

 $\label{eq:Register} \textbf{Register}, \textbf{Unregister}, \textbf{RegisterClass}, \textbf{RegistryList}, \textbf{RegistryValid}, \\ \textbf{RegistryArrayNew}$ 

# RegistryList

Get an array of registry IDs

#### **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_RegistryList ( id, class, resources )
```

#### **FUNCTION**

This function obtains an array of the registered IDs of the Registry class class. See Register for more information about DIPlib's Registry.

The following code gives an example of a class-specific register list function:

#### **ARGUMENTS**

Data type	Name	Description
dip_IntegerArray *	id	Pointer to an array of Registry IDs
dip_int	class	Registry class
dip_Resources	resources	Resources tracking structure. See ResourcesNew

#### SEE ALSO

Register, Unregister, RegisterClass, RegistryGet, RegistryValid, RegistryArrayNew

# RegistryValid

Validate an registry item

#### **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_RegistryValid ( id, class, verdict )
```

#### **FUNCTION**

This function checks whether id has been registered in the Registry in the Registry class class. If verdict is not zero, the validation information (DIP\_FALSE or DIP\_TRUE) is copied to verdict. Otherwise an error is returned in case the validation fails.

See Register for more information about DIPlib's Registry.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{int}$	id	Registry ID
$\mathtt{dip}_{-}\mathtt{int}$	class	Registry class
dip_Boolean *	verdict	Pointer to a boolean containing the validation data

#### **SEE ALSO**

Register, Unregister, RegisterClass, RegistryList, RegistryGet, RegistryArrayNew

# Resampling

623

Interpolation function

#### **SYNOPSIS**

```
#include "dip_interpolation.h"
dip_Error dip_Resampling ( in, out, zoom, shift, method )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function resmaples the input image in to out using various interpolation methods. Both a (subpixel) shift and a zoom factor are supported. The size of the output image is zoom times the size of in. If shift is zero, a shift of zero is assumed. If zoom is zero, a zoom of 1.0 is assumed.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_FloatArray	zoom	Zoom factor
dip_FloatArray	shift	Shift
dipf_Interpolation	method	Interpolation method

The dipf\_Interpolation enumaration consists of the following constants:

Name	Description
DIP_INTERPOLATION_DEFAULT	Default interpolation method
DIP_INTERPOLATION_BSPLINE	B-Spline interpolation
DIP_INTERPOLATION_FOURTH_ORDER_CUBIC	Forth order cubic interpolation
DIP_INTERPOLATION_THIRD_ORDER_CUBIC	Third order cubic interpolation
DIP_INTERPOLATION_LINEAR	Linear interpolation
DIP_INTERPOLATION_ZERO_ORDER_HOLD	Zero order hold interpolation

## **SEE ALSO**

#### Subsampling

## ResourcesFree

Free resources

#### **SYNOPSIS**

dip\_Error dip\_ResourcesFree( resources, flags )

#### **FUNCTION**

Free all resources registers in the resource tracking structure, as well as the resource tracking structure itself. To prevent errors, the resource tracking structure is set to 0. Passing a null pointer instead of a pointer to a dip\_Resources structure is allowed and silently ignored.

## **ARGUMENTS**

Data type	Name	Description
dip_Resources *	resources	The tracking structure which was used to register
		the resources that must be freed. Note the double
		pointer, allowing this routine to set your pointer to 0
dipf_ResourcesFree	flags	When set to DIP_RMRF_DONT_FREE,
		dip_ResourcesFree only frees the dip_Resources
		structure itself, not the resources associated with it

#### **SEE ALSO**

ResourcesNew, ResourcesMerge, ResourceSubscribe, ResourceUnsubscribe

# ResourcesMerge

Add one resource list to another

#### **SYNOPSIS**

dip\_Error dip\_ResourcesMerge( resources, mergee )

#### **FUNCTION**

Adds one resource list to another. This function is very useful when writing functions that will support a dip\_Resources parameter. Typically you want to allocate a number of resources and only add these to the user-supplied dip\_Resources when all these allocations have been successful. This is where ResourcesMerge comes in. Allocate a local dip\_Resources structure and register all resources with it. When no errors occured the local dip\_Resources structure can be merged with the user-supplied dip\_Resources structure. If an error did occur, simply free all local resources by calling ResourcesFree. In addition it is the convention that functions supporting resource tracking also accept a zero indicating that no tracking should be performed. When resources in dip\_ResourcesMerge is 0, the mergee tracking structure is freed, but the resources it contains are not. In this way you get support for the "resources = 0 means no tracking" convention for free.

#### **ARGUMENTS**

Data type	Name	Description
dip_Resources	resources	The dip_Resources structure with which the additional
		resources much be merged
dip_Resources *	mergee	A pointer to the dip_Resources structure containing
		the additional resources to be merged. After the merge,
		mergee is set to 0.

#### SEE ALSO

ResourcesNew, ResourcesFree, ResourceSubscribe, ResourceUnsubscribe

#### ResourcesNew

Allocate a resource tracking structure

#### **SYNOPSIS**

dip\_Error dip\_ResourcesNew( resources, noItems )

#### **FUNCTION**

This function allocates a dip\_Resources structure. The resource structure can be used to register various resources as they are allocated, provided that the allocating function allows you to register the resource. All resources allocated in this manner can be freed with a single call to ResourcesFree. Examples of functions supporting this registration scheme are ImageNew and special versions of the memory allocation routines.

Some operations consist of an initialization and a cleanup stage. These stages are often performed by separate routines to allow the user to execute his/her own operations in between. In DIPlib there usually is no directly callable cleanup function. Instead the initialization routine registers its cleanup routine with a dip\_Resources structure provided by the user. The cleanup operation is invoked through ResourcesFree.

All functions that support the registration leave you the choice not to register the resource. This is indicated by supplying a zero instead of a resource tracking structure, unless documented otherwise. The noItems parameters can be used to give the routine a hint about the number of resources you will register. The structure grows automagically whenever more resources are registered than indicated by the hint parameter.

#### **ARGUMENTS**

Data type	Name	Description
dip_Resources *	resources	This will be used to return a dip_Resources structure
dip_int	noItems	A hint about the number of resources you are planning
		to allocate. This parameter must be $\geq 2$ or 0 to
		indicate you want the default value. By the way, don't
		worry too much about this parameter, because when
		the structure turns out to be too small, it will
		automatically be expanded

#### SEE ALSO

ResourcesFree, ResourcesMerge, ResourceSubscribe, ResourceUnsubscribe, MemoryNew

## ResourceSubscribe

Track a resource

627

#### **SYNOPSIS**

dip\_Error dip\_ResourceSubscribe( resource, freeResourceHandler, resources )

#### **FUNCTION**

Track a resource. The resource must be represented by a void \*. A handler function to free the resource must be given. This function will be called through dip\_ResourcesFree with the resource as its only parameter. If dip\_ResourceSubscribe fails, the resource is not registered. It is allowed to pass a zero instead of a dip\_Resources structure, in which case dip\_ResourceSubscribe returns silently.

#### **ARGUMENTS**

Data type	Name	Description
void *	resource	The resource that must be
		registered
dip_ResourcesFreeHandler	freeResourceHandler	The handler function that will be
		invoked by dip_ResourcesFree
		to free the resource
dip_Resources	resources	dip_Resources structure to
		register the resource with

## **SEE ALSO**

ResourcesNew, ResourcesFree, ResourcesMerge, ResourceUnsubscribe

## ResourceUnsubscribe

Stop tracking a resource

## **SYNOPSIS**

dip\_Error dip\_ResourceUnsubscribe( resource, resources )

## **FUNCTION**

Stop tracking a resource. It will be removed from the dip\_Resources structure. The resource itself will not be freed. If a zero is passed instead of a resource or the dip\_Resources structure, dip\_ResourceUnsubscribe returns silently.

## **ARGUMENTS**

Data type	Name	Description
void *	resource	The resource that should no longer be tracked
dip_Resources	resources	dip_Resources structure to remove the resource from

# ${\tt RootMeanSquareError}$

difference measure

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_RootMeanSquareError ( in1, in2, mask, out )
```

#### DATA TYPES

binary, integer, float, complex

## **FUNCTION**

Calculates the root mean square difference between each pixel value of in1 and in2. Optionally the mask image can be used to exclude pixels from the calculation by setting the value of these pixels in mask to zero.

#### **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in1	First input
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input
$\mathtt{dip}_{-}\mathtt{Image}$	mask	Mask
dip_Image	out	Output

## Rotation

Interpolation function

#### **SYNOPSIS**

```
#include "dip_interpolation.h"
dip_Error dip_Rotation ( in, out, angle, method, bgval )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function rotates an 2-D image in over angle to out using three skews. The function implements the rotation in the mathmetical sense, **but** note the Y-axis is positive downwards! The rotation is over the centre of the image.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_float	angle (radians)	Rotation angle
$dipf_Interpolation$	method	Interpolation method
dip_BackgroundValue	bgval	Background value

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The dip\_BackgroundValue enumaration consists of the following flags:

Name	Description
DIP_BGV_DEFAULT	Default: fill with zeros
DIP_BGV_ZERO	Fill with zeros
DIP_BGV_MAX_VALUE	Fill with maximum value for data type
DIP_BGV_MIN_VALUE	Fill with minimum value for data type

## KNOWN BUGS

This function is only implemented for 2D images.

## SEE ALSO

Skewing

## Rotation3d

Interpolation function

#### **SYNOPSIS**

```
#include "dip_interpolation.h"
dip_Error dip_Rotation3d ( in, out, alpha, beta, gamma, method, bgval )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function rotates an 3-D image in via the three Euler angles alpha, beta, gamma to out using nine skews. The first rotation is about alpha around the initial 3-axis. The second about beta around the intermediate 2-axis and the last about gamma around the final 3-axis. The function implements the rotation in the mathmetical sense, but note the Y-axis is positive downwards! The rotation is over the centre of the image.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_float	alpha (radians)	Euler angle
dip_float	beta (radians)	Euler angle
dip_float	gamma (radians)	Euler angle
$\mathtt{dipf}_{-}\mathtt{Interpolation}$	method	Interpolation method
dip_BackgroundValue	bgval	Background value

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The dip\_BackgroundValue enumaration consists of the following flags:

Name	Description
DIP_BGV_DEFAULT	Default: fill with zeros
DIP_BGV_ZERO	Fill with zeros
DIP_BGV_MAX_VALUE	Fill with maximum value for data type
DIP_BGV_MIN_VALUE	Fill with minimum value for data type

## **KNOWN BUGS**

This function is only implemented for 3D images.

## SEE ALSO

Skewing, Rotation3dAxis

## Rotation3d Axis

Interpolation function

#### **SYNOPSIS**

```
#include "dip_interpolation.h"
dip_Error dip_Rotation3d_Axis ( in, out, angle, axis, method, bgval )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function rotates an 3-D image in over angle around axis to out using three skews. The rotation axis is 0(x), 1(y) or 2(z). The function implements the rotation in the mathmetical sense, but note the Y-axis is positive downwards! The rotation is over the centre of the image.

For backwards compatability, the macro Rotation3dAxis calls the function Rotation3d\_Axis but uses 1, 2 and 3 to select the axis of rotation.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_float	angle (radians)	Rotation angle
dip_int	axis	Rotation axis
$\mathtt{dipf}_{\mathtt{-}}\mathtt{Interpolation}$	method	Interpolation method
dip_BackgroundValue	bgval	Background value

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The dip\_BackgroundValue enumaration consists of the following flags:

Name	Description
DIP_BGV_DEFAULT	Default: fill with zeros
DIP_BGV_ZERO	Fill with zeros
DIP_BGV_MAX_VALUE	Fill with maximum value for data type
DIP_BGV_MIN_VALUE	Fill with minimum value for data type

## **KNOWN BUGS**

This function is only implemented for 3D images.

# ScalarImageNew

Allocate a scalar image

## **SYNOPSIS**

dip\_Error dip\_ScalarImageNew( newImage, dataType, dimensions, resources )

## **FUNCTION**

Allocate and forge a dip\_Image structure of the DIP\_IMTP\_SCALAR type.

## **ARGUMENTS**

Data type	Name	Description
dip_Image *	newImage	Used to return a pointer to your brand new
		dip_Image structure
dip_DataType	dataType	Data type. See DIPlib's data types
dip_IntegerArray	dimensions	Dimensions
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

ImageNew, ImageFree

## ScanFrameWork

FrameWork for scanning multiple images

#### **SYNOPSIS**

```
#include "dip_framework.h"
dip_Error dip_ScanFrameWork ( in, out, process, boundary, border, inBuffer,
outBuffer, outImage )
```

#### **FUNCTION**

This function provides a framework for scanning nofin input images and nofout output images in one dimension of the images. The dimension in which the image should be scan can be specified or left to ScanFrameWork by specifying the dimension with DIP\_MONADIC\_OPTIMAL\_DIMENSION. See SeparableFrameWork for details.

#### **ARGUMENTS**

Data type	Name	Description
dip_ImageArray	in	Array of input images
$ exttt{dip\_ImageArray}$	out	Array of output images
dip_FrameWorkProcess	process	Process
dip_BoundaryArray	boundary	Boundary conditions
dip_BorderArray	border	Border Array
dip_DataTypeArray	inBuffer	Array of dip_DataType of the input buffer
dip_DataTypeArray	outBuffer	Array of dip_DataType of each output buffer
dip_DataTypeArray	outImage	Array of dip_DataType of each output image

#### **SEE ALSO**

DIPlib's data types SeparableFrameWork, PixelTableFrameWork

#### SeededWatershed

Morphological segmentation

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_SeededWatershed ( seeds, in, mask, out, connectivity, order,
max_depth, max_size, binaryOutput )
```

DATA TYPES

integer, float

#### **FUNCTION**

Watershed segmentation with built-in region merging. max\_depth and max\_size control the merging procedure. Any region with max\_size or less pixels and with max\_depth grey-value difference or less will be merged to neighbouring regions when they touch (as opposed to build a watershed). max\_size equal to 0 means that the size of the region is not tested when merging. To avoid merging of seeds with no grey-value difference between them, set max\_size to a negative value. The regions are grown according to the connectivity parameter. See The connectivity parameter for more information. The output is either a labelled image where the pixels belonging to a catchment basin are labelled, or a binary image where the watershed pixels are 1 and the rest is 0. This is controlled by binaryOutput.

As opposed to Watershed, this function takes a seeds input image, and grows the catchment basins from there. The output image, when binaryOutput is DIP\_TRUE, will have label values as given by the seed image.

If mask is not 0, only the pixels within mask will be considered. All the other pixels will be untouched.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	seeds	Binary or labelled input image
dip_Image	in	Grey-value input image
$ ext{dip}_{-} ext{Image}$	mask	Mask image
$ ext{dip}_{-} ext{Image}$	out	Output
dip_int	connectivity	Connectivity
dipf_GreyValueSortOrder	order	Whether to grow from low to high or high
		to low
dip_float	$max_depth$	Maximum depth of a region that can be
		merged
dip_int	max_size	Maximum size of a region that can be
		merged
dip_Boolean	binaryOutput	DIP_FALSE if the output should be a
		labelled image

639

The  ${\tt dipf\_GreyValueSortOrder}$  enumeration consists of the following values:

Name	Description
DIP_GVSO_HIGH_FIRST	Process the pixels from high grey-value to low grey-value.
DIP_GVSO_LOW_FIRST	Process the pixels from low grey-value to high grey-value.

## SEE ALSO

Watershed, LocalMinima, Minima, Maxima, GrowRegions

## Select

Configurable selection function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Select ( in1, in2, in3, in4, out, selector )
```

#### DATA TYPES

binary, integer, float

## **FUNCTION**

This function can perform various pixel-by-pixel comparisons (smaller, smaller- equal, equal, not equal, greater-equal, greater) between in1 ans in2. If the result of the comparison is true, the corresponding pixel value of in3 is copied to out, otherwise it is copied from in4. In short the following operation is performed for each pixel in the five images:

```
out = in1 selector in2 ? in3 : in4
```

The images in2, in3 and in4 can be 0-D images acting as constants.

## **ARGUMENTS**

Data type	Name	Description	
dip_Image	in1	First input	
$\mathtt{dip}_{-}\mathtt{Image}$	in2	Second input	
dip_Image	in3	Third input	
dip_Image	in4	Fourth input	
dip_Image	out	Output	
dipf_Select	selector	Select flag	
Name		Description	
DIP_SELECT_LESSER		<, Lesser than	
DIP_SELECT_LESSER_EQUAL		<=, Lesser or equal	
DIP_SELECT_NOT_EQUAL		!=, Unequal	
DIP_SELECT_EQUAL		==, Equal	
DIP_SELECT_GREATER_EQUAL		L >=, Greater or equal	
DIP_SELECT_GREATER		>, Greater	

SEE ALSO

Compare, Max, Min

## SelectValue

Point Operation

## **SYNOPSIS**

```
#include "dip_point.h"
dip_Error dip_SelectValue ( in, out, value )
```

## DATA TYPES

integer, float

#### **FUNCTION**

This function returns a binary image with value 1 where in == value and value 0 elsewhere.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	out
Output image	dip_float

# SeparableConvolution

FrameWork for separable convolution filters

#### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_SeparableConvolution ( in, out, filters, bc, process )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

This function is a frontend to the lower level Convolve1d function. Each dimension can be processed by a different filter.

process may be zero, indicating that all dimensions should be processed.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_SeparableConvolutionFilter *	filters	Filters
dip_BoundaryArray	bc	Boundary conditions
dip_BooleanArray	process (0)	Dimensions to process

## **SEE ALSO**

General information about convolution SeparableFrameWork, Convolve1d

# SeparableFrameWork

FrameWork for separable filters

#### **SYNOPSIS**

```
#include "dip_framework.h"
dip_Error dip_SeparableFrameWork (in, out, boundary, border, process )
```

#### **FUNCTION**

The dip\_SeparableFrameWork function is a framework for separable filters. This function takes care of all the "administrative work" involved when processing a n-D dimensional DIPlib Image n times with a 1-D filter. In short, using this function, one has only to create an one dimension filter function and dip\_SeparableFrameWork takes care of the other stuff. The in DIPlib Image is filtered nrOfProcesses times using the information in each element of the process array. If nrOfProcesses is zero, only the first element of process is used to filter in in all its dimensions.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input image
${\tt dip\_Image}$	out	Output image
dip_BoundaryArray	boundary	Boundary conditions
dip_IntegerArray	border	Border array
dip_FrameWorkProcessArray	process	Array of dip_FrameWorkProcess structures

#### NOTE

The dip\_FrameWorkProcess structure contains the following members:

Data type	Name	Description	
dip_Boolean	process	flags specifying to do processing	
		or not	
dipf_FrameWorkMethod	frameWorkMethod	flags specifying the method of how	
		dip_SeparableFrameWork should	
		transport data from in to out	
dipf_FrameWorkOperation	frameWorkOperation	flags specifying requirements of	
		the 1-D filter function	
dip_int	processDimension	dimension of in to be processed	
dip_int	roiOrigin	ignored in current implementation	
dip_int	roiSize	ignored in current implementation	
dipf_FrameWorkFilter	FrameWorkFilterType	specifying the type of 1-D filter	
		function	
dip_FrameWorkFilter	FrameWorkFilter	pointer to the 1-D filter function	
void *	functionParameters	parameters of the 1-D filter	
		function, for all dimensions	
dip_DataType	inputBufferType	data type of input buffer	
dip_DataType	outputBufferType	data type of output buffer	
dip_DataType	suggestedOutputType	data type of output image	

The  ${\tt dipf\_FrameWorkMethod}$  enum contains the following elements:

Name	Description
DIP_FRAMEWORK_DEFAULT_METHOD	use dip_SeparableFrameWorks most optimal method
DIP_FRAMEWORK_CLASSICAL	use a classical method
DIP_FRAMEWORK_DOUBLE_STRIPE	use two buffers to store temporary results

It is strongly advised to use the  ${\tt DIP\_FRAEMWORK\_DEFAULT\_METHOD}$  method.

The  ${\tt dipf\_FrameWorkOperation}$  enum contains the following elements:

Name	Description	
DIP_FRAMEWORK_DEFAULT_OPERATION	default operation	
DIP_FRAMEWORK_IN_PLACE	filtering operation can be performed in-place. It is	
	up to dip_SeparableFrameWork whether the	
	actual filtering is done in-place	
DIP_FRAMEWORK_NO_IN_BORDER	the 1-D filter does not need border extension of	
	the input data	
DIP_FRAMEWORK_OUT_BORDER	the 1-D filter needs border extension of the output	
	data	
DIP_FRAMEWORK_WRITE_INPUT	the 1-D filter needs to write in the input data	
DIP_FRAMEWORK_USE_BUFFER_TYPES	made the input and output buffers of the	
	inputBufferType and outputBufferType data	
	type	
DIP_FRAMEWORK_NO_BUFFER_STRIDE	Create input and outpub buffers with a stride of	
	one	
DIP_FRAMEWORK_DO_NOT_ADJUST	Do not adjust the output image, just check it	
DIP_FRAMEWORK_USE_OUTPUT_TYPE	Adjust output image to the suggestedOutputType	
	data type	

The dipf_FrameWorkFilter enum contains t	the	following	elements:
--	-----	-----------	-----------

Name	Description
DIP_FRAMEWORK_SEPARABLE_FILTER	default filter type, process one line at
	the time
DIP_FRAMEWORK_TWO_LINES_SEPARABLE_FILTER	process two lines in one go
DIP_FRAMEWORK_SINGLE_OUTPUT_FILTER	this filter only needs an output buffer

The union dip\_FrameWorkFunction consists of the types

Name	Description
dip_SeparableFilter	one line filter function
dip_TwoLinesSeparableFilter	two lines filter function
dip_SingleOutputFilter	single output image filter

The functions have the following arguments: dip\_SeparableFilter

Data type	Name	Description
void *	inData	pointer to the input data
void *	outData	pointer to the output data
dip_int	elements	number of pixels in the inData array
dip_SeparableFilterParameters	params	parameter structure for the filter
		function

#### and ${\tt dip\_SeparableTwoLinesFilter}$

Data type	Name	Description
void *	inFirstLineData	pointer to the data
		of the first input
		line
void *	inSecondLineData	pointer to the data
		of the second input
		line
void *	outFirstLineData	pointer to the data
		of the first output
		line
void *	outSecondLineData	pointer to the data
		of the second
		output line
dip_int	elements	number of pixels in
		the
		inFirstLineData
		array
dip_TwoLinesSeparableFilterParameters	params	parameter structure
		for the two lines
		filter function

The inData, inFirstLineData and inSecondLineData will always point to the first pixel of the line of in that is processed. Therefore, the 1-D filter can access pixels with indices ranging from -border[dimension] up to elements + border[dimension]. If the flag DIP\_FRAMEWORK\_OUT\_BOUNDARY is specified, the same holds for the output data pointers.

The structure  $\mathtt{dip\_SeparableFilterParameters}$  contains the following elements:

Data type	Name	Description
void *	functionParameters	parameters of the 1-D filter function per
		dimension
dip_int	dimension	the dimension in which direction the input
		buffer is taken from the input image
dip_int	processNumber	number of times dip_SeparableFrameWork
		has already filtered in with an 1-D filter
		including current filtering
dip_DataType	inType	dip_DataType of the input buffer
dip_int	inStride	stride of the elements in the input array
dip_int	inPlane	plane number in case in is a binary image
dip_DataType	outType	dip_DataType of the output buffer
dip_int	outStride	stride of the elements in the output array
dip_int	outPlane	plane number in case out is a binary image
dip_int	outDimension	the dimension in which direction the output
		buffer is taken from the output image
dip_IntegerArray	position	coordinate of the first pixel of the input
		buffer in the input image

The structure  ${\tt dip\_TwoLinesSeparableFilterParameters}$  contains the following elements:

Data type	Name	Description
void *	functionParameters	parameters of the 1-D filter function per
		dimension
dip_int	dimension	the dimension in which direction the input
		buffer is taken from the input image
dip_int	processNumber	number of times dip_SeparableFrameWork
		has already filtered in with an 1-D filter
		including current filtering
dip_DataType	inType	dip_DataType of the input buffer
$\mathtt{dip}_{-}\mathtt{int}$	inStride	stride of the elements in the input array
$\mathtt{dip}_{-}\mathtt{int}$	inPlane	plane number in case in is a binary image
dip_DataType	outType	dip_DataType of the output buffer
dip_int	outStride	stride of the elements in the output array
dip_int	outPlane	plane number in case out is a binary image
dip_int	outDimension	the dimension in which direction the output
		buffer is taken from the output image
dip_IntegerArray	position	coordinate of the first pixel of the input
		buffer in the input image

The structure  $\mathtt{dip\_SingleOutputFilterParameters}$  contains the following elements:

Data type	Name	Description
void *	functionParameters	parameters of the 1-D filter function per
		dimension
dip_int	dimension	the dimension in which direction the input
		buffer is taken from the input image
dip_int	processNumber	number of times dip_SeparableFrameWork
		has already filtered in with an 1-D filter
		including current filtering
dip_DataType	type	dip_DataType of the input buffer
dip_int	stride	stride of the elements in the input array
dip_int	plane	plane number in case in is a binary image
dip_IntegerArray	position	coordinate of the first pixel of the input
		buffer in the input image

## Sharpen

Enhance an image

#### **SYNOPSIS**

```
#include "dip_derivatives.h"
dip_Error dip_Sharpen ( in, out, weight, bc, ps, sigmas, tc, flavour )
```

#### DATA TYPES

See Laplace

#### **FUNCTION**

This function enhances the high frequencies ("sharpens") of the input image in by subtracting a Laplace filtered version of in from it. The weight parameter determines by which amount the laplace information is subtracted from the original: output = input - weight \* laplace(input) The sigmas are the Gaussian smoothing parameters of the Laplace operation, and determine how strongly the high-frequency noise in in is suppressed.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image
dip_float	weight	Laplacian weight
dip_BoundaryArray	boundary	Boundary conditions
dip_BooleanArray	process (0)	Dimensions to process
dip_FloatArray	sigmas	Sigma of Gaussian
dip_float	truncation (<0)	Truncation of Gaussian
dip_DerivativeFlavour	flavour	Derivative Flavour

#### **SEE ALSO**

Laplace

### Shift

an image manipulation function

#### **SYNOPSIS**

```
#include "dip_manipulation.h"
dip_Error dip_Shift ( in, out, shift, killNy )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

This function shifts an image in the Fourier Domain. All frequiencies larger than the Nyquist frequency are set to zero if killNy is true. It performs:

```
out = Real(InverseFourierTransform(GeneratePhase(shift) * FourierTransform( in ))
```

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
dip_Image	out	Output image
dip_FloatArray	shift	Shift array
dip_Boolean	killNy	set frequencies > Nyquist to zero?

#### **SEE ALSO**

Crop, Wrap, FourierTransform, Real

## Sigma

Adaptive uniform smoothing filter

#### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_Sigma ( in, out, se, boundary, filterSize, shape, sigma, outputCount )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

The Sigma filter is an adaptive Uniform smoothing filter. The value of the pixel underinvestigation is replaced by the average of the pixelvalues in the filter region (as specified by filterSize, shape and se) which lie in the interval +/- 2 sigma from the value of the pixel that is filtered. If outputCount is DIP\_TRUE, the output values represent the number of pixel over which the average has been calculated. When threshold is DIP\_TRUE, the pixel intensities are being thresholded at +/- 2 sigma, when it is set to DIP\_FALSE, the intensities are weighted with the Gaussian difference with the intensity of the central pixel.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterSize	Filter sizes
dip_FilterShape	shape	Filter shape
dip_float	sigma	Sigma
dip_Boolean	outputCount	Output the Count

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

### NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

# Sign

Arithmetic function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Sign ( in, out )
```

#### DATA TYPES

binary, integer, **float** 

#### **FUNCTION**

Computes the sign of the input image values, and outputs a signed integer typed image. The sign of zero is defined as zero.

### **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in	Input
dip_Image	out	Output

### SEE ALSO

Abs, Ceil, Floor, Truncate, Fraction, NearestInt

### SimulatedAttenuation

Simulation of the attenuation process

#### **SYNOPSIS**

#include "dip\_microscopy.h"

 $dip\_Error\ dip\_SimulatedAttenuation$  ( in, out, fAttenuation, bAttenuation, NA, refIndex, zxratio, oversample, rayStep )

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function simulates an attenuation based on the model of a CSLM, using a ray tracing method.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image
dip_float	fAttenuation	Forward attenuation factor
dip_float	bAttenuation	Backward attenuation factor
dip_float	NA	Numerical aperture
dip_float	refIndex	Refractive index
dip_float	zxratio	Z/X sampling ratio
$\mathtt{dip}_{-}\mathtt{int}$	oversample	Ray casting oversampling
dip_float	rayStep	Ray step

# SingleOutputFrameWork

FrameWork for generation functions

#### **SYNOPSIS**

```
#include "dip_framework.h"
dip_Error dip_SingleOutputFrameWork ( out, processBoundary, processBorder, process )
```

#### **FUNCTION**

This function is a frontend on the SeparableFrameWork. It provides an easier interface for filters that only need to scan an single output image. The dimension in which the image should be scan can be specified or left to SingleOutputFrameWork by specifying the dimension with DIP\_MONADIC\_OPTIMAL\_DIMENSION.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	out	Output
dip_Boundary	processBoundary	ProcessBoundary
dip_int	processBorder	ProcessBorder
dip_FrameWorkProcess	process	Process

# ${\tt SingularValueDecomposition}$

Singular value decomposition

#### **SYNOPSIS**

```
#include "dip_svd.h"
dip_Error dip_SingularValueDecomposition ( in, sz, u, s, d )
```

#### DATA TYPES

float, dfloat

#### **FUNCTION**

Computes the SVD of the ImageArray in, such that in = u \* s \* transpose(t), with s being diagonal. The size of the in matrix is passed to the function via the IntegerArray sz. If the input is of size m x n, then the outputs must be u: n x m, s: n x n; d: n x n.

#### **ARGUMENTS**

Data type	Name	Description
dip_ImageArray	in	Input
dip_IntegerArray	sz	Matrix size of Input
$\mathtt{dip}_{-}\mathtt{ImageArray}$	u	Output
dip_ImageArray	s	Output
dip_ImageArray	d	Output

### Sinh

trigonometric function

### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Sinh ( in, out )
```

#### DATA TYPES

binary, integer, float

### **FUNCTION**

Computes the hyperbolic sine of the input image values.

### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	out	Output

### **SEE ALSO**

Sin, Cos, Tan, Asin, Acos, Atan, Atan2, Cosh, Tanh

# Skewing

Interpolation function

#### **SYNOPSIS**

```
#include "dip_math.h" #include "dip_interpolation.h"
dip_Error dip_Skewing ( in, out, shear, skew, axis, method, bgval,
periodicSkew )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function skews the axis axis of in over an angle angle to out using the interpolation method method. The skew is over the centre of the image. If periodicSkew is set to DIP\_TRUE, the output image will be of the same size as the input image, and its pixels in the skew dimension wrapped around the image boundaries. bgval is not used in this case.

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	out	Output image
dip_float	shear (radians)	Shear angle
dip_int	skew	Skew dimension
dip_int	axis	Skew axis
$dipf_{-}Interpolation$	method	Interpolation method
dip_BackgroundValue	bgval	Background value
dip_Boolean	periodicSkew	Skew using periodic image boundaries

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The  ${\tt dip\_BackgroundValue}$  enumaration consists of the following flags:

Name	Description
DIP_BGV_DEFAULT	Default: fill with zeros
DIP_BGV_ZERO	Fill with zeros
DIP_BGV_MAX_VALUE	Fill with maximum value for data type
DIP_BGV_MIN_VALUE	Fill with minimum value for data type

### **SEE ALSO**

Rotation, Rotation3d, Rotation3dAxis

# SmallObjectsRemove

Remove small objects from an image

#### **SYNOPSIS**

```
#include "dip_measurement.h"
dip_Error dip_SmallObjectsRemove ( in, out, threshold )
```

#### DATA TYPES

#### integer

#### **FUNCTION**

This function removes from the labeled image in those objects whose size (measured in the number of pixels) is smaller than threshold.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input image
${\tt dip\_Image}$	out	Output image
$\mathtt{dip}_{-}\mathtt{int}$	threshold	Minimum object size

#### SEE ALSO

Measure, ObjectToMeasurement, Label

### SobelGradient

A linear gradient filter

#### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_SobelGradient ( in, out, boundary, processDim )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

The SobelGradient filter computes a finite difference gradient  $(1\ 0\ -1)/2$  in the processDim, and performs a local  $(1\ 2\ 1)/4$  smoothing in the other dimensions. Note that in 2D, this differs by a multiplication factor of 1/8 to the original definition by Sobel.

#### **ARGUMENTS**

Data type	Name	Description
$dip_{-}Image$	in	Input
dip_Image	out	Output
dip_BoundaryArray	boundary	Boundary conditions
dip_int	processDim	ProcessDim

#### SEE ALSO

General information about convolution

FiniteDifference, Uniform, Gauss, SeparableConvolution, Convolve1d, Derivative

### Sort

Sort a block of data

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_Sort ( data, size, algorithm, dataType )
```

#### **FUNCTION**

Sorts a block of data (of size size and data type dataType ) using the algorithm specified by algorithm.

#### **ARGUMENTS**

Data type	Name	Description
void *	data	Data
dip_int	size	Size
dip_Sort	algorithm	Sort algorithm
dip_DataType	dataType	Data type. See DIPlib's data types

The sortType parameter is one of:

Name	Description
DIP_SORT_DEFAULT	Default sort algorithm
DIP_SORT_QUICK_SORT	Quick sort
DIP_SORT_DISTRIBUTION_SORT	Distribution sort
DIP_SORT_INSERTION_SORT	Insertion sort

#### **SEE ALSO**

General information about sorting

DistributionSort, InsertionSort, QuickSort, ImageSort, SortIndices, SortIndices16, ImageSortIndices

# SortAnything

Sort data of any type

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_SortAnything ( data, size, compareFunction, swapFunction,
tmpData, algorithm )
```

#### **FUNCTION**

Sorts a block of data (of size size) using the algorithm specified by algorithm. This routine requires the user to write two functions in order to fully implement the sorting procedure. These are SortCompareFunction and SortSwapFunction.

#### **ARGUMENTS**

Data type	Name	Description
void *	data	Data
dip_int	size	Size
dip_SortCompareFunction	compareFunction	Function for comparing two data
		points
dip_SortSwapFunction	swapFunction	Function for swapping two data points,
		or copying one to the other
void *	tmpData	Pointer to a variable of the same type
		as the data, used as temporary space
		by some of the algorithms
dip_Sort	algorithm	Sort algorithm

#### **SEE ALSO**

General information about sorting

 ${\tt QuickSortAnything,\,SortCompareFunction,\,SortSwapFunction}$ 

## SortCompareFunction

Typedef for comparison function (sorting)

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Boolean (*dip_SortCompareFunction) ( data1, index1, data2, index2 )
```

#### **FUNCTION**

A function of this type must be supplied to the sorting algorithms for data of arbitrary type. It should return DIP\_TRUE if data1[index1] > data2[index2].

Example:

```
dip_Boolean MyComplexCompare( void *data1, dip_int index1, void *data2, dip_int index2 )
   dip_complex *cmplx1, *cmplx2;
   dip_float magnitude1, magnitude2;
   cmplx1 = data1;
   cmplx2 = data2;
   cmplx1 += index1;
   cmplx2 += index2;
   magnitude1 = sqrt( cmplx1->re * cmplx1->re + cmplx1->im * cmplx1->im );
   magnitude2 = sqrt( cmplx2->re * cmplx2->re + cmplx2->im * cmplx2->im );
   if ( magnitude1 > magnitude2 )
      return( DIP_TRUE );
   }
   else
      return( DIP_FALSE );
   }
}
```

### **ARGUMENTS**

Data type	Name	Description
void *	data1	Pointer to first data array
dip_int	index1	Index to element in first data array
void *	data2	Pointer to second data array
dip_int	index2	Index to element in second data array

## SEE ALSO

General information about sorting

 ${\tt SortAnything,\,QuickSortAnything,\,SortSwapFunction}$ 

### SortIndices

Sort indices to a block of data

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_SortIndices ( data, indices, size, algorithm, dataType, indexType )
```

#### **FUNCTION**

Sorts a list of indices rather than the data itself using the algorithm specified by algorithm.

#### **ARGUMENTS**

Data type	Name	Description	
void *	data	Data	
void *	indices	Indices	
dip_int	size	Size	
dip_Sort	algorithm	Sort algorithm	
dip_DataType	dataType	Data type. See DIPlib's data types	
dip_DataType	indexType	Data type of the index array. Must be either	
		DIP_DT_SINT32 or DIP_DT_SINT16.	

The sortType parameter is one of:

Name	Description
DIP_SORT_DEFAULT	Default sort algorithm
DIP_SORT_QUICK_SORT	Quick sort
DIP_SORT_DISTRIBUTION_SORT	Distribution sort
DIP_SORT_INSERTION_SORT	Insertion sort

#### **SEE ALSO**

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, ImageSort, SortIndices 16, ImageSortIndices}$ 

### SortIndices16

Sort indices to a block of data

#### **SYNOPSIS**

```
#include "dip_sort.h"
dip_Error dip_SortIndices16 ( data, indices, size, algorithm, dataType )
```

#### **FUNCTION**

Sorts a list of (16 bit) indices rather than the data itself using the algorithm specified by algorithm.

#### **ARGUMENTS**

Data type	Name	Description	
void *	data	Data	
dip_sint16 *	indices	Indices	
dip_int	size	Size	
dip_Sort	algorithm	Sort algorithm	
dip_DataType	dataType	Data type. See DIPlib's data types	

The sortType parameter is one of:

Name	Description
DIP_SORT_DEFAULT	Default sort algorithm
DIP_SORT_QUICK_SORT	Quick sort
DIP_SORT_DISTRIBUTION_SORT	Distribution sort
DIP_SORT_INSERTION_SORT	Insertion sort

#### **SEE ALSO**

General information about sorting

 ${\tt DistributionSort, InsertionSort, QuickSort, Sort, ImageSort, SortIndices, ImageSortIndices}$ 

## SortSwapFunction

Typedef for swap and copy function (sorting)

#### **SYNOPSIS**

```
#include "dip_sort.h"
void (*dip_SortSwapFunction) ( data1, index1, data2, index2, copy )
```

#### **FUNCTION**

A function of this type must be supplied to the sorting algorithms for data of arbitrary type. It should swap data1[index1] and data2[index2] if copy = DIP\_FALSE, and copy data1[index1] to data2[index2] if copy = DIP\_TRUE.

Example:

}

}

return;

cmplx1->im = tmpValue.im;

```
void dip_MyComplexSwap( void *data1, dip_int index1, void *data2, dip_int index2, dip_Boolear
{
   dip_complex *cmplx1, *cmplx2, tmpValue;
   cmplx1 = data1;
   cmplx2 = data2;
   cmplx1 += index1;
   cmplx2 += index2;
   if ( copy == DIP_TRUE )
   {
      cmplx2->re = cmplx1->re;
      cmplx2->im = cmplx1->im;
   }
   else
   {
      tmpValue.re = cmplx2->re;
      tmpValue.im = cmplx2->im;
      cmplx2->re = cmplx1->re;
      cmplx2->im = cmplx1->im;
      cmplx1->re = tmpValue.re;
```

### **ARGUMENTS**

Data type	Name	Description		
void *	data1	Pointer to first data array		
dip_int	index1	Index to element in first data array		
void *	data2	Pointer to second data array		
dip_int	index2	Index to element in second data array		
dip_Boolean	сору	if DIP_FALSE, swap data. if DIP_TRUE copy data from data1 to		
		data2

# StablePixelHeapFree

Destroy heap structure

#### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapFree ( heap )
```

#### **FUNCTION**

Frees all data associated to heap and sets heap to 0.

#### **ARGUMENTS**

Data type	Name	Description
dip_StablePixelHeap *	heap	The heap structure

#### **SEE ALSO**

StablePixelHeapNew, PixelHeapNew, PixelQueueNew, StablePixelHeapPush, StablePixelHeapIop, StablePixelHeapIsEmpty

# ${\tt StablePixelHeapIsEmpty}$

Query heap

#### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapIsEmpty ( heap, result )
```

#### **FUNCTION**

Checks to see if there are any items on the heap. See **StablePixelHeapNew** for information on the heap data structure.

#### **ARGUMENTS**

Data type	Name	Description
dip_StablePixelHeap heap		The heap structure
dip_Boolean *	result	Set to true if there are no items in the heap

#### **SEE ALSO**

StablePixelHeapNew, PixelHeapNew, PixelQueueNew, StablePixelHeapFree, StablePixelHeapPush, StablePixelHeapPop

## StablePixelHeapNew

Create a new heap structure

#### **SYNOPSIS**

#include "dip\_pixelqueue.h"
dip\_Error dip\_StablePixelHeapNew ( heap, ndims, blocksize, order, resources )

#### **FUNCTION**

This function allocates space for a new dip\_StablePixelHeap structure. Memory allocated is tracked in resources. The heap is dimensioned to hold pixels from an ndims-dimensional image, and initially enough space is allocated for blocksize elements. The heap will be expanded as necessary when used.

The heap stores the coordinates, the value and the pointer to a pixel in an image. Note that the value does not need to equal the data pointed to by the pointer. ndims can be set to zero, in which case no coordinates are stored; this does not affect the function of the value and the pointer.

A heap is a priority queue data structure. Just like a queue, items can be added (pushed) and subtracted (popped). However, in the priority queue the item popped is always the higherst priority one: either the one with the highest-valued item (order is DIP\_GVSO\_HIGH\_FIRST) or lowest-valued item (order is DIP\_GVSO\_LOW\_FIRST). When various identically-valued items are stored on the heap, they will be extracted in the same order as they were insterted (FIFO - first in, first out). If this order is unimportant (such as for the GrowRegionsWeighted algorithm, use the more efficient dip\_PixelHeap instead. See PixelHeapNew for information on the unstable heap structure.

#### **ARGUMENTS**

Data type	Name	Description
dip_StablePixelHeap *	heap	The newly allocated heap structure
dip_int	ndims	Image dimensionality
dip_int	blocksize	Size of each allocation block
dipf_GreyValueSortOrder	order	Determines the heap's sort order
dip_Resources	resources	Resources tracking structure. See
		ResourcesNew

The dipf\_GreyValueSortOrder enumeration consists of the following values:

Name	Description
DIP_GVSO_HIGH_FIRST	Process the pixels from high grey-value to low grey-value.
DIP_GVSO_LOW_FIRST	Process the pixels from low grey-value to high grey-value.

#### **IMPLEMENTATION**

This data structure is implemented identically to PixelHeapNew (see that function's description for details), but an insertion order value is attached to each pixel pushed onto the heap. This is used to maintain stability.

### **SEE ALSO**

PixelHeapNew, PixelQueueNew, StablePixelHeapFree, StablePixelHeapPush, StablePixelHeapPop, StablePixelHeapIsEmpty

# StablePixelHeapPop

Pop item onto heap

#### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapPop ( heap, coords, pointer, value )
```

#### **FUNCTION**

Pops the next pixel from the heap. See StablePixelHeapNew for information on the heap data structure. coords is a pointer to an array of dip\_ints, such as that obtained with dip\_IntegerArray->array. It should have as many elements as the image dimensionality. If the stack was created with ndims set to 0, the coords pointer is ignored. coords, pointer and value can be NULL if you are not interested in either those values.

#### **ARGUMENTS**

Data type	Name	Description
dip_StablePixelHeap	heap	The heap structure
dip_int *	coords	Receives the coordinates of the popped item
void **	pointer	Receives the pointer of the popped item
dip_sfloat *	value	Receives the value of the popped item

#### **SEE ALSO**

StablePixelHeapNew, PixelHeapNew, PixelQueueNew, StablePixelHeapFree, StablePixelHeapPush, StablePixelHeapIsEmpty

# StablePixelHeapPush

Push item onto heap

#### **SYNOPSIS**

```
#include "dip_pixelqueue.h"
dip_Error dip_StablePixelHeapPush ( heap, coords, pointer, value )
```

#### **FUNCTION**

Pushes a pixel onto the heap. See StablePixelHeapNew for information on the heap data structure. All 3 values coords, pointer and value are stored, except if the heap was created with ndims set to 0, in which case the coords pointer is ignored.

coords is a pointer to an array of dip\_ints, such as that obtained with dip\_IntegerArray->array. It should have as many elements as the image dimensionality. pointer is a pointer to any memory location, and value is the value to be used when sorting.

#### **ARGUMENTS**

Data type	Name	Description
dip_StablePixelHeap	heap	The heap structure
dip_int *	coords	Coordinates to be pushed
void *	pointer	Pointer to be pushed
dip_sfloat	value	Value to be pushed

#### **SEE ALSO**

### StandardDeviation

statistics function

#### **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_StandardDeviation ( in, mask, out, ps )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

Calculates the standard deviation of the pixel values over all those dimensions which are specified by ps.

#### **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in	Input
${\tt dip\_Image}$	mask (0)	Mask
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
dip_BooleanArray	ps (0)	Dimensions to project

#### **SEE ALSO**

# StringAppend

Append a string to another

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringAppend ( str1, str2, cstr )
```

## **FUNCTION**

Concatenates str1 and str2 and puts the result in str1, which is increased in size if necessary. If str2 is 0, cstr is used instead.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{S}}\mathtt{tring}$	str1	First string
dip_String	str2	Second string
char *	cstr	Second string

## **SEE ALSO**

 ${\tt StringCat}, {\tt StringCompare}, {\tt StringCompareCaseInsensitive}, {\tt StringCopy}, {\tt StringCrop}, {\tt StringNew}, {\tt StringReplace}, {\tt UnderscoreSpaces}$ 

# StringArrayCopy

Copy a string array

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringArrayCopy ( new, src, resources )
```

## **FUNCTION**

This function copies the complete src string array to new.

## **ARGUMENTS**

Data type	Name	Description
dip_StringArray *	new	Pointer to the destination dip_StringArray structure
dip_StringArray	src	Source string array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# SEE ALSO

# StringArrayFree

Array free function

## **SYNOPSIS**

dip\_Error dip\_StringArrayFree ( array )

## **FUNCTION**

This function frees \*array, and sets array to zero.

## **ARGUMENTS**

Data type	Name	Description
dip_ImageArray *	array	string array

## **SEE ALSO**

StringArrayNew, StringArrayCopy

ArrayFree, IntegerArrayFree, FloatArrayFree, ComplexArrayFree,
BoundaryArrayFree, FrameWorkProcessArrayFree, DataTypeArrayFree, ImageArrayFree,
BooleanArrayFree, VoidPointerArrayFree, StringArrayFree, CoordinateArrayFree

# StringArrayNew

Allocate an array of strings

#### **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringArrayNew ( array, size, stringSize, init, resources )
```

## **FUNCTION**

This function allocates an array of strings. size specifies the size of the array, stringSize the size of the individual strings, which are allocated too. If StringSize is zero, and init is not, the strings in the array are initialised with init (in size and content). If both stringSize and init are zero, strings of zero length are created. (see StringNew).

#### **ARGUMENTS**

Data type	Name	Description
dip_StringArray *	array	Pointer to the array
dip_int	size	Size of the array
dip_int	stringSize	Size of the strings
char *	init	Initialisation string
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

StringArrayFree, StringArrayCopy

# StringCat

Concatenate two strings

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringCat ( newStr, str1, str2, cstr, resources )
```

## **FUNCTION**

Concatenates str1 and str2 and puts the result in newStr, which is allocated. If str2 is 0, cstr is used instead.

## **ARGUMENTS**

Data type	Name	Description
dip_String *	newStr	Destination
dip_String	str1	First string
dip_String	str2	Second string
char *	cstr	Second string
dip_Resources	resources	Resources tracking structure. See ResourcesNew

## **SEE ALSO**

 ${\tt StringAppend, StringCompare, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, StringReplace, UnderscoreSpaces}$ 

# StringCompare

Compare two strings

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringCompare ( orig, copy, verdict )
```

## **FUNCTION**

This function uses the strcmp function to compare orig and copy. If the strings are different, an error is generated, or verdict obtains the value DIP\_FALSE, if it is not zero.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{L}}\mathtt{String}$	orig	The original string
dip_String	сору	The fake (or not) string
dip_Boolean *	verdict	Verdict of the comparison

## **SEE ALSO**

 ${\tt StringAppend, StringCat, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, StringReplace, UnderscoreSpaces}$ 

# ${\tt StringCompareCaseInsensitive}$

Compare two strings without minding case

#### **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringCompareCaseInsensitive ( orig, copy, verdict )
```

## **FUNCTION**

This function uses the strcasecmp (or stricmp) function to compare orig and copy. If the strings are different, an error is generated, or verdict obtains the value DIP\_FALSE, if it is not zero.

## **ARGUMENTS**

Data type	Name	Description
dip_String	orig	The original string
dip_String	сору	The fake (or not) string
dip_Boolean *	verdict	Verdict of the comparison

## **SEE ALSO**

StringAppend, StringCat, StringCompare, StringCopy, StringCrop, StringNew, StringReplace, UnderscoreSpaces

# StringCopy

Copy a String

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringCopy ( new, src, resources )
```

## **FUNCTION**

Thsi function copies string src to new.

## **ARGUMENTS**

Data type	Name	Description
dip_String *	new	Pointer to a destination dip_String strcture
dip_String	src	Source string
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# **SEE ALSO**

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCrop, StringNew, StringReplace, UnderscoreSpaces

# StringCrop

Crop a string

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringCrop ( str, length )
```

## **FUNCTION**

Crops str to length characters.

## **ARGUMENTS**

Data type	Name	Description
$dip\_String$	str	String to be cropped
$\mathtt{dip}_{\mathtt{-}}\mathtt{int}$	length	New string length

## SEE ALSO

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCopy, StringNew, StringReplace, UnderscoreSpaces

# StringFree

Free a string

# **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringFree ( void )
```

# **FUNCTION**

This function frees a string data structure that has been allocated using StringNew.

## **ARGUMENTS**

Data type	Name	Description
dip_String *	string	Pointer to the string to be freed

# SEE ALSO

StringNew

# StringNew

Allocate a string

#### **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringNew ( string, size, init, resources )
```

## **FUNCTION**

This function allocates a string of size size. If init is not zero, its contents is copied into the new string. If size is zero, and init is not, the size of string is made equal to init plus one.

## **ARGUMENTS**

Data type	Name	Description
dip_String *	string	Pointer to the new string
dip_int	size	Size of the string
char *	init	Initialisation string
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# StringReplace

Replace the contents of one string with that of another

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_StringReplace ( str1, str2, cstr )
```

## **FUNCTION**

Replaces the content of str1 with str2. str1 is increased in size if necessary. If str2 is 0, cstr is used instead.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{S}}\mathtt{tring}$	str1	Destination string
dip_String	str2	Source string
char *	cstr	Source string

## **SEE ALSO**

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, UnderscoreSpaces

## StructureTensor2D

Two dimensional Structure Tensor

#### **SYNOPSIS**

```
#include "dip_structure.h"
dip_Error dip_StructureTensor2D( in, mask, orientation, energy, 11, 12,
anisotropy1, anisotropy2, boundary, gradSpec, gradSigmas, tensorSpec,
tensorSigmas )
```

#### DATA TYPES

#### integer, float

## **FUNCTION**

This function computes the Structure Tensor (ST) at each point in the image. For a description of this technique see the references. There are two stages in the computation. The first stage computes the gradient vector at each point, using Derivative with parameters gradSpec and gradSigmas. The second stage, the tensor smoothing, is also performed using Derivative (with order = 0). The parameters used are tensorSpec and tensorSigmas.

If a mask image is given, a technique called normalised convolution (see references) is used to "fill in" the missing data.

The routine has a number of output images. Each of these can be set to zero. If set to zero, the corresponding result will not be computed. The following quantities are computed by this routine:

orientation	Orientation. Lies in the interval
	(-pi/2,pi/2).
energy	Sum of the two eigenvalues 11 and 12.
11	The largest eigenvalue.
12	The smallest eigenvalue.
anisotropy1	Measure for local anisotropy: ( 11 - 12 )
	/ ( 11 + 12 ).
anisotropy2	Measure for local anisotropy: 1 - 12 /
	11.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	mask	Mask image (0=missing data)
$\mathtt{dip}_{-}\mathtt{Image}$	orientation	Orientation
$\mathtt{dip}_{-}\mathtt{Image}$	energy	Energy (11+12)
dip_Image	11	Largest eigenvalue
dip_Image	12	Smallest eigenvalue
dip_Image	anisotropy1	Local anisotropy: (11-12)/(11+12)
dip_Image	anisotropy2	Local anisotropy: 1-12/11
dip_BoundaryArray	boundary	Boundary conditions
dip_DerivativeSpec	gradSpec	Parameters for derivative to compute gradient
		(see DerivativeSpec data structure)
dip_FloatArray	gradSigmas	Sigmas of derivative to compute gradient
		Sigma of derivative to compute gradient
dip_DerivativeSpec	tensorSpec	Parameters for Gaussian for tensor smoothing
		(see DerivativeSpec data structure)
dip_FloatArray	tensorSigmas	Sigmas of Gaussian for tensor smoothing
		Sigma of Gaussian for tensor smoothing

# TestObjectAddNoise

TestObject generation function

#### **SYNOPSIS**

#include "dip\_generation.h"

dip\_Error dip\_TestObjectAddNoise ( object, noisy, background, backvalue,
gaussianNoise, poissonNoise, snr, conversion, variance, random )

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function adds a mixture of Gaussian and Poisson noise to a testobject at a specified signal-to-noise ratio. The SNR is defined as the average object energy divided by the average noise power.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	object	Input Object Image
$\mathtt{dip}_{-}\mathtt{Image}$	noisy	Output Image
dip_Image	background	Background Image
dip_float	backvalue	Constant Background Value
dip_float	gaussianNoise	Relative Amount of Gaussian Noise
dip_float	poissonNoise	Relative Amount of Poisson Noise
dip_float	snr	Signal to Noise Ratio
dip_float *	conversion (0)	Pointer to the Poisson Conversion Factor
dip_float *	variance (0)	Pointer to the Gaussian Variance
dip_Random *	random	Pointer to a random value structure

## **SEE ALSO**

TestObjectCreate, TestObjectModulate, TestObjectBlur

# TestObjectBlur

TestObject generation function

#### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_TestObjectBlur ( object, psf, convolved, xNyquist, testPSF )
```

## DATA TYPES

binary, integer, float

## **FUNCTION**

This function blurs a testobject with a Gaussian psf, with a two dimensional in focus diffraction limited incoherent PSF or with an user-supplied PSF. The xNyquist parameter specifies the oversampling factor of the incoherent PSF and Gaussian PSF. The sigma of the Gaussian PSF is equal to 0.9 \* xNyquist.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	object	Input Object Image
dip_Image	psf	User supplied PSF
dip_Image	convolved	Output Image
dip_float	xNyquist	Oversampling Factor
dipf_TestPSF	testPSF	TestPSF

The dipf\_TestPSF enumaration consists of the following flags:

Name	Description
DIP_TEST_PSF_GAUSSIAN	Gaussian PSF
DIP_TEST_PSF_INCOHERENT_OTF	in-focus, diffraction limited, incoherent PSF
DIP_TEST_PSF_USER_SUPPLIED	User supplied PSF with the psf image
DIP_TEST_PSF_NONE	no blurring

## **SEE ALSO**

TestObjectCreate, TestObjectModulate, TestObjectAddNoise

# TestObjectCreate

TestObject generation function

#### **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_TestObjectCreate ( object, testObject, objectHeight,
objectRadius, scale, scaleRadius, scaleAmplitude, objSigma, position, random)
```

#### DATA TYPES

Output: sfloat

## **FUNCTION**

This function can generate an aliasing free object (ellips, box, ellipsoid shell, box shell) or uses an user-supplied object. The generated objects have their origin at the center in the image, but can be generated with a sub-pixel random shift around the center, to average out dicretization effects over several instances of the same generated object. Optinally the generated object can be convolved with an isotropic Gaussian with a width specified by objSigma. Elliptical objects are only supported for images with a dimsnionality equal or less than three. The position boolean variable specifies whether a subpixel random shift should be applied to the object. This can be used to average out digitisation error over a repetition of the generation of the same object.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	object	Output Object Image
dipf_TestObject	testObject	Type of Test Object
dip_float	objectHeight	Object Height
dip_float	objectRadius	Object Radius
dip_FloatArray	scale	Relative Radii for each dimension
dip_float	scaleRadius	ScaleRadius
dip_float	scaleAmplitude	ScaleAmplitude
dip_float	objSigma	Sigma of Gaussian Object Blur
dip_Boolean	position	Random Subpixel Position Shift
dip_Random *	random	Pointer to a random value structure

# TestObjectModulate

TestObject generation function

## **SYNOPSIS**

```
#include "dip_generation.h"
dip_Error dip_TestObjectModulate ( in, out, modulation, modulationDepth )
```

## DATA TYPES

Output: sfloat

## **FUNCTION**

This function adds a sine modulation to a test object, with modulation the modulation frequency and modulationDepth the modulation depth.

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{-}}\mathtt{Image}$	in	Input
dip_Image	out	Output
dip_FloatArray	modulation	Modulation Frequency
dip_float	modulationDepth	ModulationDepth

## **SEE ALSO**

TestObjectCreate, TestObjectBlur, TestObjectAddNoise

## Threshold

Point Operation

#### **SYNOPSIS**

```
#include "dip_point.h"
dip_Error dip_Threshold ( in, out, threshold, foreground, background, binaryOutput )
```

## DATA TYPES

integer, float

## **FUNCTION**

This function thresholds an image at the threshold value. If the boolean binaryOutput is true, Threshold will produce a binary image. Otherwise an image of the same type as the input image is produced, with the pixels set to either foreground or background. In other words: out = ( in >= threshold ? foreground: background)

## **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
dip_Image	out	Output image
dip_float	threshold	Threshold value
dip_float	foreground	Foreground value
dip_float	background	Background value
dip_Boolean	binaryOutput	Convert output image to binary

# TikhonovMiller

Image restoration filter

## **SYNOPSIS**

```
#include "dip_restoration.h" #include "dip_transform.h"
dip_Error dip_TikhonovMiller ( in, psf, out, reg, background, method, var, lambda, flags )
```

## **FUNCTION**

The TikhonovMiller restoration filter is a linear least squares restoration algorithm.

## **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input image
dip_Image	psf	Point spread function image
dip_Image	out	Output image
dip_Image	reg	Regularisation filter image
dip_Image	background (0)	Background image
dipf_RegularizationParameter	method	Method used to determine the
		regularisation parameter
dip_float	var	Noise variance
dip_float *	lambda	Regularisation parameter
$ ext{dipf}_{-} ext{ImageRestoration}$	flags	Restoration flags

## TimerGet

Timing functions

## **SYNOPSIS**

```
#include "dip_timer.h"
dip_Error dip_TimerGet ( timer )
```

## **FUNCTION**

This function get four Timer values elapsed since the last call to TimerSet. The elapsed clock time is measured in a low (1 second) resolution, and in a high (microseconds) resolution. However, this latter timer can only produce reliable results within 36 minutes after the first (!) call to TimerSet has been made. The other two timer measure the amount of system and user time used by the program since the last call to TimerSet.

## **ARGUMENTS**

Data type	Name	Description
dip_Timer *	timer	Pointer to a dip_Timer struct

## **SEE ALSO**

TimerSet

# TimerSet

Timing functions

# **SYNOPSIS**

```
#include "dip_timer.h"
dip_Error dip_TimerSet ( timer )
```

# **FUNCTION**

This function resets four timers that can be obtained by TimerGet.

## **ARGUMENTS**

Data type	Name	Description
dip_Timer *	timer	pointer to a dip_Timer structure

# SEE ALSO

TimerGet

# Tophat

Morphological high-pass filter

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_Tophat ( in, out, se, boundary, filterParam, shape, edgeType,
polarity )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

The top-hat is the difference between a morphological operation and the original image, comparable to a high-pass filter. Which operation is used can be chosen through the dip\_MphEdgeType and dip\_MphTophatPolarity parameters.

The rectangular, elliptic and diamond structuring elements are "flat", i.e. these structuring elements have a constant value. For these structuring elements, filterParam determines the sizes of the structuring elements. When shape is set to DIP\_FLT\_SHAPE\_PARABOLIC, filterParams specifies the curvature of the parabola. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is used as structuring element. It can be either a binary or a grey-value image, but be careful: it is converted to the same data type as the input image, and might therefore be clipped or loose precision. It is required (in the current implementation) that the structuring element be odd in size. Its origin is the center.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

## **ARGUMENTS**

Data type	Name	Description
${ t dip\_Image}$	in	Input
${\tt dip\_Image}$	out	Output
$dip_{-}Image$	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape
dip_MphEdgeType	edgeType	edgeType
dip_MphTophatPolarity	polarity	polarity

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

The enumerator  ${\tt dip\_MphEdgeType}$  contains the following constants:

Name	Description
DIP_MPH_TEXTURE	Response is limited to edges in texture
DIP_MPH_OBJECT	Response is limited to object edges
DIP_MPH_BOTH	All edges produce equal response

The enumerator dip\_MphTophatPolarity contains the following constants:

Name	Description
DIP_MPH_TEXTURE	Response is limited to edges in texture
DIP_MPH_OBJECT	Response is limited to object edges
DIP_MPH_BOTH	All edges produce equal response

## **SEE ALSO**

tpi.h

Type iterator

#### **SYNOPSIS**

#include "dip\_tpi.h"

#### **FUNCTION**

Type iterator. For each data type specified by the define DIP\_TPI\_ALLOW, dip\_tpi.h will include the file specified by the define DIP\_TPI\_FILE. If DIP\_TPI\_ALLOW is not defined the file will be included for all data types. DIP\_TPI\_TYPES must be defined as a logical OR of identifier flags and identifier group flags, as given in DIPlib's data types and the table below. During each "iteration" the main symbols defined by dip\_tpi.h are DIP\_TPI, DIP\_TPI\_DATA\_TYPE, DIP\_TPI\_IDENTIFIER and DIP\_TPI\_EXTENSION. The following table shows how these are defined for each data type:

DIP_TPI	DIP_TPI_DATA_TYPE		DIP_TPI_EXTENSION
		DIP_TPI_IDENTIFIER	
dip_bin8	DIP_DT_BIN8	DIP_DTID_BIN8	_b8
dip_bin16	DIP_DT_BIN16	DIP_DTID_BIN16	_b16
dip_bin32	DIP_DT_BIN32	DIP_DTID_BIN32	_b32
dip_uint8	DIP_DT_UINT8	DIP_DTID_UINT8	_u8
dip_uint16	DIP_DT_UINT16	DIP_DTID_UINT16	_u16
dip_uint32	DIP_DT_UINT32	DIP_DTID_UINT32	_u32
dip_sint8	DIP_DT_SINT8	DIP_DTID_SINT8	_s8
dip_sint16	DIP_DT_SINT16	DIP_DTID_SINT16	_s16
dip_sint32	DIP_DT_SINT32	DIP_DTID_SINT32	_s32
dip_sfloat	DIP_DT_SFLOAT	DIP_DTID_SFLOAT	_sfl
dip_dfloat	DIP_DT_DFLOAT	DIP_DTID_DFLOAT	_dfl
dip_scomplex	DIP_DT_SCOMPLEX	DIP_DTID_SCOMPLEX	_SCX
dip_dcomplex	DIP_DT_DCOMPLEX	DIP_DTID_DCOMPLEX	_dcx

Using this include file it is possible to compile source code for different data types. We recommend that instead of splitting your code into two files, one for generic code and one for type specific code, that you use dip\_tpi.h to let the source file include itself. This also prevents dependency problems with makefiles. A source file that includes itself through dip\_tpi.h should have the following format:

```
contents of example.c:
#ifndef DIP_TPI
```

#include "diplib.h"

```
#define DIP_TPI_FILE "example.c"
#include "dip_tpi.h"

/* This is where the generic code should be */
#else

/* This is where the type specific code should be */
#endif
```

In addition to the main defines as described above, there are a number of macro's that are defined by dip\_tpi.h:

DIP_TPI_FUNC (function name)	attaches the current type suffix to the	
	function name.	
DIP_TPI_DEFINE ( function name )	equivalent to: dip_Error DIP_TPI_FUNC(	
	function name ) useful for function	
	definitions.	
DIP_TPI_DECLARE ( function name )	equivalent to: dip_Error DIP_TPI_FUNC(	
	function name ) useful for function	
	declarations. Don't forget the trailing ";".	
DIP_TPI_NAME ( function name )	attaches the current type suffix to the	
	function name and puts double quotes	
	around the result, thus creating a string.	

There are also a couple of defines that are only available for some of the data types:

When DIP_TPI is		
dip_sfloat	DIP_TPI_CAST_R2C is defined as	
	dip_scomplex	
dip_dfloat	DIP_TPI_CAST_R2C is defined as	
	dip_dcomplex	
dip_scomplex	DIP_TPI_CAST_C2R is defined as dip_sfloat	
dip_dcomplex	DIP_TPI_CAST_C2R is defined as dip_dfloat	

Other type iterators may be created by making a copy of the dip\_tpi.h file and replacing DIP\_TPI throughout the file by a different name for the new type iterator.

## **ARGUMENTS**

Name	Description	
DIP_TPI_ALLOW	logical OR of data type identifier and identifier group flags to indicate	
	for which data types the file should be included	
DIP_TPI_FILE	Name of the file to be included by dip_tpi.h

## Truncate

Arithmetic function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Truncate ( in, out )
```

## DATA TYPES

binary, integer, **float** 

#### **FUNCTION**

Computes the truncation of the input image values, and outputs a signed integer typed image.

## **ARGUMENTS**

Data type	Name	Description	
${\tt dip\_Image}$	in	Input	
dip_Image	out	Output

# UnderscoreSpaces

Replace spaces with underscores

## **SYNOPSIS**

```
#include "dip_string.h"
dip_Error dip_UnderscoreSpaces ( string )
```

#### **FUNCTION**

This function replaces spaces in string with underscores. This function works in-place.

## **ARGUMENTS**

Data type	Name	Description	
$dip\_String$	string	String to be examined	

## **SEE ALSO**

StringAppend, StringCat, StringCompare, StringCompareCaseInsensitive, StringCopy, StringCrop, StringNew, StringReplace

## Uniform

Uniform filter

#### **SYNOPSIS**

```
#include "dip_linear.h"
dip_Error dip_Uniform ( in, out, se, boundary, filterParam, shape )
```

#### DATA TYPES

binary, integer, float, complex

#### **FUNCTION**

This functions implements an uniform convolution filter with support for various filter shapes.

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterParam	Filter parameters
dip_FilterShape	shape	Filter shape

The enumerator dip\_FilterShape contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

## UniformNoise

Generate an image disturbed by uniform noise

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_UniformNoise ( in, out, lowerBound, upperBound, random )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Generate an image disturbed by additive uniform noise. See <code>UniformRandomVariable</code> for more information on the random number generator.

#### **ARGUMENTS**

Data type	Name	Description	
dip_Image	in	Input	
dip_Image	out	Output	
dip_float	lowerBound	Lower bound of the uniform distribution the noise is	
		drawn from	
dip_float	upperBound	upperBound Upper bound of the uniform distribution the noise is	
		drawn from	
dip_Random *	random	Pointer to a random value structure	

#### **EXAMPLE**

Get a image with additive uniform noise as follows:

```
dip_Image in, out;
dip_float lower, upper;
dip_Random random;

lower = 1.0;
upper = 10.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_UniformNoise( in, out, lower, upper, &random ));
```

# SEE ALSO

 $\label{thm:comparison} Uniform Random Variable, Random Seed, Random Seed Vector, \\ Gaussian Noise, Poisson Noise, Binary Noise$ 

## UniformRandomVariable

Uniform random variable generator

#### **SYNOPSIS**

```
#include "dip_noise.h"
dip_Error dip_UniformRandomVariable ( random, lowerBound, upperBound, output)
```

#### **FUNCTION**

Generate an uniform distributed random variable. See RandomVariable for more information on the random number generator.

#### **ARGUMENTS**

Data type	Name	Description		
dip_Random *	random	Pointer to a random value structure		
dip_float	lowerBound	and Lower bound of the uniform distribution the variable is		
		drawn from		
dip_float	upperBound	Upper bound of the uniform distribution the variable is		
		drawn from		
dip_float*	output	output		

#### **EXAMPLE**

Get a uniform random variable as follows:

```
dip_Random random;
dip_float lower, upper, value;

lower = -1.0;
upper = 1.0;
DIPXJ( dip_RandomSeed( &random, 0 ));
DIPXJ( dip_UniformRandomVariable( &random, lower, upper, &value ));
```

# Unregister

729

Remove a registry item

## **SYNOPSIS**

```
#include "dip_registry.h"
dip_Error dip_Unregister ( id, class )
```

#### **FUNCTION**

This function removes the Registry information of the ID of the Registry class class. See Register for more information about DIPlib's Registry.

#### **ARGUMENTS**

Data type	Name	Description	
dip_int	id	Registry ID	
dip_int	class	Registry class	

## **SEE ALSO**

Register, RegistryList, RegistryGet, RegistryArrayNew

# UpperEnvelope

Upper envelope transform (a flooding and an algebraic closing)

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_UpperEnvelope ( in, out, bottom, labels, connectivity,
max_depth, max_size )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

The Upper envelope transform produces a flooding of the input image (which is an algebraic closing). See any article by F. Meyer for further explanations.

The Upper envelope is based on the watershed transform, each region being filled up to the level where it meets a neighbouring region. See Watershed for information on the parameters.

The bottom image is a second output image that contains the whole watershed region painted with the lowest value in it. It is useful for stretching the input image: (out - in) / (in - bottom). labels returns the label image used during region growing.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
dip_Image	out	Output
dip_Image	bottom	Optional output
$\mathtt{dip}_{-}\mathtt{Image}$	labels	Optional output
dip_int	connectivity	Connectivity
dip_float	max_depth	Maximum depth of a region that can be merged
dip_int	max_size	Maximum size of a region that can be merged

#### SEE ALSO

Watershed, LocalMinima

## Variance

statistics function

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Variance ( in, mask, out, ps )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

Calculates the variance of the pixel values over all those dimensions which are specified by ps.

## **ARGUMENTS**

Data type Name		Description
dip_Image in		Input
dip_Image	mask (0)	Mask
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output
dip_BooleanArray ps (0)		Dimensions to project

## **SEE ALSO**

From images to scalars

Sum, Mean, StandardDeviation, MeanModulus, SumModulus, MeanSquareModulus, Maximum, Minimum, Median, Percentile

## VarianceFilter

Sample Variance Filter

#### **SYNOPSIS**

```
#include "dip_filtering.h"
dip_Error dip_VarianceFilter ( in, out, se, boundary, filterSize, shape )
```

#### DATA TYPES

binary, integer, float

#### **FUNCTION**

This function calculates for every pixel the sample variance of the pixels in the filter window (it size specified by filterSize).

If shape is not equal to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, se is allowed to be set to zero. When shape is set to DIP\_FLT\_SHAPE\_STRUCTURING\_ELEMENT, filterParam is ignored, (and can be set to zero).

#### **ARGUMENTS**

Data type	Name	Description
dip_Image	in	Input
dip_Image	out	Output
dip_Image	se	Structuring element
dip_BoundaryArray	boundary	Boundary conditions
dip_FloatArray	filterSize	Filter sizes
dip_FilterShape	shape	Filter shape

The enumerator  ${\tt dip\_FilterShape}$  contains the following constants:

Name	Description
DIP_FLT_SHAPE_DEFAULT	default structuring element, same as
	DIP_FLT_SHAPE_RECTANGULAR
DIP_FLT_SHAPE_RECTANGULAR	rectangular structuring element
DIP_FLT_SHAPE_ELLIPTIC	elliptic structuring element
DIP_FLT_SHAPE_DIAMOND	diamond shaped structuring element
DIP_FLT_SHAPE_PARABOLIC	parabolic structuring element
DIP_FLT_SHAPE_STRUCTURING_ELEMENT	use se as structuring element

# NOTE

The filter shape  ${\tt DIP\_FLT\_SHAPE\_PARABOLIC},$  as well as custom grey-value shapes, are not supported.

## VectorDistanceTransform

Euclidean vector distance transform

#### **SYNOPSIS**

```
#include "dip_distance.h"
dip_Error dip_VectorDistanceTransform ( in, outx, outy, outz, distance, border, method )
```

#### DATA TYPES

#### binary

#### **FUNCTION**

This function produces the vector components of the Euclidean distance transform. These are stored in the output images, one for each dimension of the input image. See the EuclideanDistanceTransform for detailed information about the parameters.

To compute the Euclidean distance from the vector components produced by this function, one needs to multiply each component with the sampling distance, square the result, sum the results for all components and take the square root of the sum.

#### **ARGUMENTS**

Data type	Name	Description
${ t dip\_Image}$	in	Input image
$ exttt{dip\_ImageArray}$	out	Output images
dip_FloatArray	distance	Sampling distances
dip_Boolean	border	Image border type
dipf_DistanceTransform	method	Transform method

dipf\_DistanceTransform defines the following distance transform types:

Name	Description
DIP_EDT_FAST	fastest, but most errors
DIP_EDT_TIES	slower, but fewer errors
DIP_EDT_TRUE	slow, uses lots of memory, but is "error free"
DIP_EDT_BRUTE_FORCE	gives a result from which errors are calculated for the other
	methods. This method is extremly slow and should only be used
	for testing purposes.

# VoidPointerArrayCopy

Copy an array

#### **SYNOPSIS**

dip\_Error dip\_VoidPointerArrayCopy ( dest, src, resources )

#### **FUNCTION**

This function copies the void pointer array src to dest. The array dest is created by this function as well.

#### **ARGUMENTS**

Data type	Name	Description
${ t dipIntegerArray} *$	dest	Destination array
dip_IntegerArray	src	Source array
dip_Resources	resources	Resources tracking structure. See ResourcesNew

# VoidPointerArrayFind

Find value in array

#### **SYNOPSIS**

dip\_Error dip\_VoidPointerArrayFind ( array, value, index, found )

#### **FUNCTION**

Finds a value in an array and "returns" its index in the array. If found is zero, VoidPointerArrayFind will produce an error if value is not found, otherwise found obtains the search result (DIP\_FALSE if value is not found).

#### **ARGUMENTS**

Data type	Name	Description
dip_VoidPointerArray	array	Array to find value in
void *	value	Value to find
dip_int *	index	Index of the found value
dip_VoidPointer *	found	Value found or not

#### **SEE ALSO**

## Watershed

Morphological segmentation

#### **SYNOPSIS**

```
#include "dip_morphology.h"
dip_Error dip_Watershed ( in, mask, out, connectivity, max_depth, max_size,
binaryOutput )
```

#### DATA TYPES

integer, float

#### **FUNCTION**

Watershed segmentation with built-in region merging. max\_depth and max\_size control the merging procedure. Any region with max\_size or less pixels and with max\_depth grey-value difference or less will be merged to neighbouring regions when they touch (as opposed to build a watershed). max\_size equal to 0 means that the size of the region is not tested when merging. The regions are grown according to the connectivity parameter. See The connectivity parameter for more information. The output is either a labelled image where the pixels belonging to a catchment basin are labelled, or a binary image where the watershed pixels are 1 and the rest is 0. This is controlled by binaryOutput.

If mask is not 0, only the pixels within mask will be considered. All the other pixels will be marked as watershed pixels.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{\mathtt{I}}\mathtt{Image}$	in	Input
dip_Image	mask	Mask
dip_Image	out	Output
dip_int	connectivity	Connectivity
dip_float	max_depth	Maximum depth of a region that can be merged
dip_int	max_size	Maximum size of a region that can be merged
dip_Boolean	binaryOutput	DIP_FALSE if the output should be a labelled image

# Wiener

Image Restoration Filter

#### **SYNOPSIS**

```
#include "dip_restoration.h"
dip_Error dip_Wiener ( in, psf, signalPower, noisePower, out, flags )
```

#### **FUNCTION**

This function performs an image restoration using the Wiener filter. The Wiener filter is the linear restoration filter that is optimal in mean square error sense.

#### **ARGUMENTS**

Data type	Name	Description
$\mathtt{dip}_{-}\mathtt{Image}$	in	Input image
dip_Image	psf	Point spread function image
dip_Image	signalPower	SignalPower image
dip_Image	noisePower	NoisePower image
dip_Image	out	Output image
dipf_Restoration	flags	Restoration flags

Xor

logic operation

## **SYNOPSIS**

```
#include "dip_math.h"
dip_Error dip_Xor ( in1, in2, out )
```

## DATA TYPES

binary, integer

# **FUNCTION**

The function Xor performs the logic XOR operation between the corresponding pixels in in1 and in2, and stores the result in out.

## **ARGUMENTS**

Data type	Name	Description
${\tt dip\_Image}$	in1	First binary input image
dip_Image	in2	Second binary input image
$\mathtt{dip}_{-}\mathtt{Image}$	out	Output image

Chapter 3

Assorted topics

# 3.1 Boundary conditions

Neighbourhood operations pose a problem. What happens when the neighbourhood operator operates near the border of the image and needs data from the area outside the image? The usual solution, also adopted by DIPlib, is to silently extend the image. There are various ways of extending the boundary. Below is a list of the possible methods. More details can be found in the user guide. Note that not all functions support all of these.

Name	Description
DIP_BC_SYM_MIRROR	Symmetric mirroring
DIP_BC_ASYM_MIRROR	Asymmetric mirroring
DIP_BC_PERIODIC	Periodic copying
DIP_BC_ASYM_PERIODIC	Asymmetric periodic copying
DIP_BC_ADD_ZEROS	Extending the image with zeros
DIP_BC_ADD_MAX_VALUE	Extending the image with +infinity
DIP_BC_ADD_MIN_VALUE	Extending the image with -infinity

# 3.2 Compression methods for image files

#### The dipio\_Compression structure

The structure dipio\_Compression specifies the compression method to use when writing an image file, and contains the following elements:

Data type	Name	Description
dipio_CompressionMethod	method	Compression method
dip_int	level	Compression parameter, dependent on method

dipio\_CompressionMethod is an enum with the known compression methods. File formats typically only support one or a few of these, and most of these methods do not have a parameter to set, in which case level is ignored. If an unsupported compression method is selected, no compression is done. The dipio\_CompressionMethod has the following values:

Name	Description
DIPIO_CMP_DEFAULT	Default compression method for the file format
DIPIO_CMP_NONE	No compression
DIPIO_CMP_GZIP	ZIP compression, using zlib. The level parameter is between
	1 and 10, 1 being the faster, lesser compression and 10 being
	the slower, higher compression.
DIPIO_CMP_DEFLATE	Deflate (same as DIPIO_CMP_GZIP)
DIPIO_CMP_COMPRESS	Using UNIX's "compress" utility, which uses the LZW
	algorithm
DIPIO_CMP_LZW	LZW compression (same as DIPIO_CMP_COMPRESS)
DIPIO_CMP_JPEG	Lossy JPEG compression. The level parameter is between 1
	and 100, higher numbers giving better quality output but
	larger files.
DIPIO_CMP_PACKBITS	PackBits
DIPIO_CMP_THUNDERSCAN	ThunderScan
DIPIO_CMP_NEXT	NeXT
DIPIO_CMP_CCITTRLE	CCITT RLE
DIPIO_CMP_CCITTRLEW	CCITT RLE/W
DIPIO_CMP_CCITTFAX3	CCITT Group 3
DIPIO_CMP_CCITTFAX4	CCITT Group 4

Thus only DIPIO\_CMP\_GZIP and DIPIO\_CMP\_JPEG currently have a level to set.

#### Supported compression methods for the various file formats

The TIFF file writer understand the methods DIPIO\_CMP\_NONE, DIPIO\_CMP\_DEFLATE, DIPIO\_CMP\_LZW, DIPIO\_CMP\_JPEG, DIPIO\_CMP\_PACKBITS, DIPIO\_CMP\_THUNDERSCAN, DIPIO\_CMP\_NEXT, DIPIO\_CMP\_CCITTRLE, DIPIO\_CMP\_CCITTRLEW, DIPIO\_CMP\_CCITTFAX3 and DIPIO\_CMP\_CCITTFAX4. It defaults to DIPIO\_CMP\_DEFLATE. The level parameter is currently not used.

The ICS file writer understands DIPIO\_CMP\_NONE, DIPIO\_CMP\_GZIP and DIPIO\_CMP\_COMPRESS, although DIPIO\_CMP\_COMPRESS is currently not implemented. It defaults to DIPIO\_CMP\_GZIP.

The GIF file writer only understands <code>DIPIO\_CMP\_LZW</code>. The compression method selected is simply ignored.

The JPEG file writer only understands <code>DIPIO\_CMP\_JPEG</code>. The compression method selected is simply ignored.

All other file writers do not compress, and simply ignore the compression method requested.

# 3.3 DerivativeSpec data structure

## **STRUCTURE**

This structure is an aggregate of common parameters for derivative operators. Its current definition is:

```
typedef struct
{
    dip_DerivativeFlavour flavour;
    dip_float truncation;
} dip_DerivativeSpec;
```

The enumerator flavour parameter is one of:

Name	Description
DIP_DF_DEFAULT	Default derivative flavour (==DIP_DF_FIRGAUSS)
DIP_DF_FIRGAUSS	Gaussian family, FIR implementation, Gauss
DIP_DF_IIRGAUSS	Gaussian family, IIR implementation, GaussIIR
DIP_DF_FTGAUSS	Gaussian family, FT implementation, GaussFT
DIP_DF_FINITEDIFF	Finite difference implementation, FiniteDifferenceEx

#### **SEE ALSO**

StructureTensor2D, Derivative

# 3.4 DIPlib's data types

Pixel values are represented by	different types,	called data	types.	DIPlib supports	the data
types given in the following tab	ole:				

data type	dip_DataType	data type	suffix
		identifier	
dip_bin8	DIP_DT_BIN8	DIP_DTID_BIN8	_b8
dip_bin16	DIP_DT_BIN16	DIP_DTID_BIN16	_b16
dip_bin32	DIP_DT_BIN32	DIP_DTID_BIN32	_b32
dip_uint8	DIP_DT_UINT8	DIP_DTID_UINT8	_u8
dip_uint16	DIP_DT_UINT16	DIP_DTID_UINT16	_u16
dip_uint32	DIP_DT_UINT32	DIP_DTID_UINT32	_u32
dip_sint8	DIP_DT_SINT8	DIP_DTID_SINT8	_s8
dip_sint16	DIP_DT_SINT16	DIP_DTID_SINT16	_s16
dip_sint32	DIP_DT_SINT32	DIP_DTID_SINT32	_s32
dip_sfloat	DIP_DT_SFLOAT	DIP_DTID_SFLOAT	_sfl
dip_dfloat	DIP_DT_DFLOAT	DIP_DTID_DFLOAT	_dfl
dip_scomplex	DIP_DT_SCOMPLEX	DIP_DTID_SCOMPLEX	_SCX
dip_dcomplex	DIP_DT_DCOMPLEX	DIP_DTID_DCOMPLEX	_dcx

The data types can be divided into five classes: the binary, unsigned integer, signed integer, floating point and complex classes. Different data types in the same class (e.g. dip\_uint8 and dip\_uint16) provide a different range of values they can represent.

The complex data types are defines as follows:

```
typedef struct
{
    dip_sfloat re;
    dip_sfloat im;
} dip_scomplex;

typedef struct
{
    dip_dfloat re;
    dip_dfloat im;
} dip_dcomplex;
```

The binary data types are simply aliases for a set of corresponding unsigned integer types. The reason for having a separate typedef for the binary types is that they are not used like ordinary integers. Each bit of the integer can store one binary value. When manipulating binary data, care must be taken not to change any of the other bits of the integer used for storing it.

The dip\_DataType enumeration is used to represent data types symbolically. It is used in dip\_Image's to indicate what the data type of the image is. Data type identifiers are used by the type iterator (see tpi.h) and overload schemes (see ovl.h and overload.h). Type suffixes are used to give type specific routines a unique name. Using a standard set of suffixes enables the type iterator and overload schemes to deal with these type specific routines. The dip\_DataType enumeration, data type identifiers and suffixes can be found in the table above.

In addition to the data type identifiers for individual data types, there are also defines to represent an entire group. These are given in the following table:

Data type identifier group	data types
DIP_DTGID_UINT	unsigned integer
DIP_DTGID_UNSIGNED	unsigned integer
DIP_DTGID_SINT	signed integer
DIP_DTGID_INT	signed and unsigned integer
DIP_DTGID_INTEGER	signed and unsigned intege
DIP_DTGID_FLOAT	floating-point
DIP_DTGID_REAL	integer and floating-point
DIP_DTGID_COMPLEX	complex floating-point
DIP_DTGID_SIGNED	signed integer, floating-point and complex
DIP_DTGID_BINARY	binary
DIP_DTGID_ALL	all

 ${\tt DataTypeGetInfo}$ 

# 3.5 Description of DIPlib's pixel tables

Pixel tables provide an efficient way to encode a multi-dimensional binary object. DIPlib's dip\_PixelTable implements this using runlength encoding (in 2-D this coding scheme is known as pxy-tables).

A DIPlib pixel table is a structure (defined in dip\_pixel\_table.h) that incorporates a link-list of runlengths. Each run-length consists of a n-D coordinate (integer array) and the length of the run along the X dimension. All the runlengths in total encode the binary object.

#### **LITERATURE**

See section 3.6, "Contour representations", in Fundamentals of Image Processing.

I.T. Young, R.L. Peverini, P.W. Verbeek and P.J. van Otterloo, A New Implementation for Binary and Minkowski Operators, Computer Graphics and Image Processing, Volume 17, No. 3, 189-210, 1981

# 3.6 File formats recognized by dipIO

#### The Registry

A number of file reading and writing functions are included in dipIO. These are registered in the ImageReadRegistry and the ImageWriteRegistry. Through this registry, ImageRead and ImageWrite are able to read from and write to any registered file format. You can add your own functions to these (the interface functions for this are not documented yet), thereby increasing the possibilities of ImageRead and ImageWrite.

Below you can find a list of currently supported file formats for both reading and writing. To obtain the format ID from the registry, you need to include the specified file and call the specified function.

## Reading

These are the file formats currently supported for reading:

DIP*lib* function reference 757

format	include file	registry ID	dimension-	colour	data types
		retrieval	ality		
		function			
ICS (Image			any	yes	any
Cytometry	dipio_ics.h	$ ext{dipio}_{ ext{ReadIC}}$	SID		
Standard)					
TIFF			2D	yes	any
(Tagged	dipio_tiff.h	dipio_ReadTI	FFID		
Image File

# ${\sf Writing}$

These are the file formats currently supported for writing:

format	include file	registry ID retrieval function	dimension- ality	colour	data types
ICS v1 (Image Cytometry Standard)	dipio_ics.h	dipio_WriteI	any CSv1ID	yes	any, binXX converted to uintXX
ICS v2 (Image Cytometry Standard)	dipio_ics.h	dipio_WriteI	any CSv2ID	yes	any, binXX converted to uintXX
TIFF (Tagged Image File Format)	dipio_tiff.h	dipio_WriteT	2D IFFID	yes	any in grey-value, uint8 in colour
JPEG (JPEG File Interchange Format)	dipio_jpeg.h	dipio_WriteJ	2D PEGID	yes	uint8
GIF (Graphics Interchange Format)	dipio_gif.h	dipio_WriteG	2D IFID	no	uint8
CVS (Comma Separated Values)	dipio_csv.h	dipio_WriteC	2D SVID	no	any except complex
FLD (AVS field file)	dipio_fld.h	dipio_WriteF	any LDID	no	any
PS (PostScript)	dipio_ps.h	dipio_WriteP	2D	yes	uint8, others automati- cally converted
EPS (Encapulated PostScript)	dipio_ps.h	dipio_WriteE	2D PSID	yes	uint8, others automati- cally converted

# 3.7 From images to scalars

Within DIPlib all data, i.e. multi-dimensional data, such as images, and scalar, are all represented by the same object: the image. Scalars are stored as zero dimensional images. Examine, for example, the following code to compute the sum over all the grey values:

```
dip_Image img;
dip_Image value;
...
dip_Sum ( img, 0, value, 0 );
```

Which stores the sum over all the pixel values of img in the 0-D image value. We often want to directly manipulate scalars, in which case we need to extract the value. This can be accomplished easily with the GetInteger, GetFloat or the GetComplex functions:

```
dip_Image img;
dip_Image valueimg;
dip_float value;
...
dip_Sum ( img, 0, valueimg, 0 );
dip_GetFloat ( valueimg, &value, 0 );
printf ( "The sum is: %f\n", value );
```

## 3.8 General information about convolution

Convolution can be explained in just a few words: it is a local weighted average (the weights can be negative). This of course does not explain how to use it or what its properties are. For this we refer to the following sources:

Ian T. Young, Jan J. Gerbrands and Lucas J. van Vliet, Fundamentals of Image Processing. Alan V. Oppenheim, Alan S. Willsky and I.T. Young, "Signals and Systems", Prentice-Hall, 1983.

Anil K. Jain, "Fundamentals of Digital Image Processing", Prentice-Hall, 1989.

"The Digital Signal Processing Handbook", Vijay K. Madisetti and Douglas B. Williams (eds), CRC Press + IEEE Press, 1998.

Kenneth R. Castleman, "Digital Image Processing", Prentice-Hall, 1996.

# 3.9 General information about sorting

There are two kinds of sorting routines in DIPlib. The first sorts a one-dimensional array of data, the second sorts a set of indices to a one-dimensional array of data. The result of the sort routines can be summarised as follows:

```
Sort: data[ i ] <= data[ i + 1 ]
Sort indices: data[ indices[ i ] ] <= data[ indices[ i + 1 ] ]</pre>
```

Note that the number of indices does not have to be equal to the amount of pixels in the image, it may be either smaller or larger. The indices themselves should of course "point" to a valid pixel.

The sorting algorithms are described in the following reference:

Donald E. Knuth, "The Art of Computer Programming, volume 3: Sorting and Searching", second edition, Addison-Wesley, 1998.

# 3.10 Information about dyadic operations

There are two types of dyadic operations. First there are operations such as Add, Sub, etc... which take two input images. The second category consists of functions such as AddFloat, AddComplex etc... The data type of the output image given the data types of the input images is given by the following table:

	dcomplex	scomplex	dfloat	sfloat	sint32	sint16
dcomplex						
scomplex	dcomplex	scomplex	dcomplex	scomplex	scomplex	scomplex
dfloat	dcomplex	dcomplex	dfloat	dfloat	dfloat	dfloat
sfloat	dcomplex	scomplex	dfloat	sfloat	sfloat	sfloat
sint32	dcomplex	scomplex	dfloat	sfloat	sint32	sint32
sint16	dcomplex	scomplex	dfloat	sfloat	sint32	sint16
sint8	dcomplex	scomplex	dfloat	sfloat	sint32	sint16
uint32	dcomplex	scomplex	dfloat	sfloat	sint32	sint32
uint16	dcomplex	scomplex	dfloat	sfloat	sint32	sint16
uint8	dcomplex	scomplex	dfloat	sfloat	sint32	sint16
binary	dcomplex	scomplex	dfloat	sfloat	sint32	sint16
	sint8	uint32	uint16	uint8	binary	
dcomplex	dcomplex	dcomplex	dcomplex	dcomplex	dcomplex	
scomplex	scomplex	scomplex	scomplex	scomplex	scomplex	
dfloat	dfloat	dfloat	dfloat	dfloat	dfloat	
sfloat	sfloat	sfloat	sfloat	sfloat	sfloat	
sint32	sint32	sint32	sint32	sint32	sint32	
sint16	sint16	sint32	sint16	sint16	sint16	
sint8	sint8	sint32	sint16	sint8	sint8	
uint32	sint32	uint32	uint32	uint32	uint32	
uint16	sint16	uint32	uint16	uint16	uint16	
uint8	sint8	uint32	uint16	uint8	uint8	
binary	sint8	uint32	uint16	uint8	sint8	

The output data type of an operation involving an image and a constant of one of the types: dip\_complex, dip\_float, dip\_int, is given by the following table:

	dip_complex	dip_float	dip_int
dcomplex	dcomplex	dcomplex	dcomplex

# 3.11 The image structure

#### DESCRIPTION

dip\_Image is the structure that is used to store images in DIPlib. It contains a number of fields that are used to describe an image. The type field stores the type of the image using a dip\_ImageType enumeration. Currently scalar images are the only supported type (DIP\_IMTP\_SCALAR). The DIP\_IMTP\_ALIEN type is used internally by DIPlib for creating interfaces to other packages. Whether the other fields in the dip\_Image are meaningful depends on the image type. A dip\_Image may contain fields specific to the current image type. These will be discussed on the pages pertaining to the type in question. The standard fields that are always present are:

field type	short description	access functions	
$ extstyle{dip_ImageType}$	The image type	ImageGetType,	
		ImageSetType	
$ extstyle{dip\_ImageState}$	The image state	(none)	
dip_DataType	Data type used to store	ImageGetDataType,	
	pixel values	ImageSetDataType	
$ exttt{dip\_IntegerArray}$	Dimensions of the image	ImageGetDimensions,	
		ImageGetDimensionality,	
		ImageSetDimensions	
void *	Pointer to the pixel data	ImageGetData	
dip_int	Plane number, for binary	ImageGetPlane	
	images		
$ exttt{dip\_IntegerArray}$	Stride array (see below)	ImageGetStride	

Pixel values are stored in the data type specified by the data type field. For a list of possible data types see DIPlib's data types.

The dimensionality of the image and the size of each individual dimension is stored in the dimensions Array.

The data pointer points to the pixel at the origin of the image. For each dimension the stride array holds the interleave between two neighbouring pixels in memory. The following equation may be used to compute the address of a pixel at a coordinate specified by an array called <code>cor[]</code>:

A dip\_Image structure does not necessarily have pixel data associated with it. When a dip\_Image does not contain pixel data, it is said to be in the "raw" state. A dip\_Image that does contain data, is said to be "forged". For binary images the plane field holds the number of the bit in which the binary data is stored. Access to the fields of a dip\_Image is

DIP*lib* function reference 765

restricted to a number of functions, which are given in the table above. The "set" functions can only be used on "raw" images.

# 3.12 The connectivity parameter

DIPlib uses a different name for the various possible connectivites than you might be used to. This is to generalize this parameter to images of any dimensionality. It is defined as follows: if connectivity is 1 all pixels for which only one coordinate differs from the pixel's coordinates by maximally 1 are considered neighbours; if it is 2, all pixels for which one or two coordinates differ maximally 1 are considered neighbours. The connectivity can never be larger than the image dimensionality.

In terms of the obsolete connectivity definitions we have:

In 2-D	this connectivity	corresponds to	and forms this
			structuring
			element
	1	4 connectivity	diamond
	2	8 connectivity	square
	-1	4-8 connectivity	octagon
	-2	8-4 connectivity	octagon
In 3-D	this connectivity	corresponds to	and forms this
			structuring
			element
	1	6 connectivity	octahedron
	2	18 connectivity	cuboctahedron
	3	26 connectivity	cube
	-1	6-26 connectivity	small rhombicuboc-
			tahedron
	-3	26-6 connectivity	small rhombicuboc-
			tahedron

The negative connectivities are only defined for the functions in binary morphology such as **BinaryDilation** and **BinaryErosion**. These alternate steps with different connectivity to produce a better approximation to an isotropic structuring element.
